## **EXECUTIVE SUMMARY**

This traffic analysis report has been prepared on behalf of the Town of Bay Harbor Islands and serves as a Project Traffic Analysis Report (PTAR) for the improvement of Broad Causeway in Miami-Dade County, Florida, from east of Bayshore Drive and West Broadview Drive. The report provides the traffic data collection, existing operational analysis, existing safety analysis, traffic forecasting, future operational analysis, and future safety analysis.

The 0.78-mile study segment of Broad Causeway is an urban minor arterial that begins east of North Bayshore Drive (North Miami) and extends east to the intersection of SR-922 and West Broadview Drive (Bay Harbor Islands). The project ties into state-maintained facilities on either end with the same 4-lane typical section to match the existing condition.

The purpose of this project PTAR is to evaluate the mobility, operations, and safety of Broad Causeway and summarize the travel impacts of proposed typical sections, project limit tie-ins, access changes near the existing Chevron gas station, and proposed Shared Use Path (SUP) along the Broad Causeway.

The years for corridor and intersection performance was Existing 2023, Opening 2030, and Design 2050.

A historical safety review was conducted using five years of complete crash records occurring within the study limits between January 1, 2018 and March 1, 2023. Crash data and crash reports were obtained from the Signal Four Analytics (Signal4) database and reviewed in accordance with FDOT Safety Crash Data Guidance.

Future traffic design volumes were developed by applying a growth rate derived from Southeast Florida Regional Planning Model (SERPM) travel demand forecasting, historical growth rates, and population projections to the existing 2023 traffic volume counts.

The project included opening and design year build alternatives. The objective of the build alternatives was to evaluate the mobility, operations, and safety impacts of the Broad Causeway improvement. The proposed four-lane divided bridge typical section includes increasing the travel lanes from 10-feet to 11-feet, introduction of a concrete median, increasing inside shoulder width to 4-feet and outside shoulder to 8-feet. In addition, a 14-foot shared use path would be included on the north side of the bridge, separated from the shoulder by a concrete barrier wall.

The build alternative also changes the way traffic enters and exits the Chevron gas station. Due to the elevation change from the bridge improvement the build now includes frontage roads that provide access between the Broad Causeway mainline and the gas station access driveways. The analysis needs due to these new movements include locations where traffic merge and diverge, as well as two stopped-controlled intersections between vehicles entering and exiting the frontage roads. For future year analysis, the no-build and build through volumes along Broad Causeway were assumed to be equal due to the number of travel lanes remaining the same.

Based on the traffic performance analysis, when comparing the no-build and build alternatives the entire project limit Level of Service (LOS) and travel speed is improved and within FDOT performance targets. In the no-build alternative 2050 delays at Chevron gas station access driveways are at LOS D or better. In the proposed build alternative, the merge and diverge areas on the frontage roads

around the gas station are estimated to operate as LOS B or better, the proposed stop-controlled intersections are estimated to operate as a LOS A, and the overall segment is a LOS A based on arterial travel speeds.

The impacts to multimodal mobility were conducted for existing and build configurations. Based on the multimodal analysis, the proposed build reconfigurations improve the Level of Traffic Stress (LTS) for pedestrians and bicyclist. The LTS for pedestrians and bicyclist improved to a LTS of 1 with the proposed addition of a shared use path, which is separated from Broad Causeway, improving the safety and comfortability for multimodal movement.

## 1.0 Introduction

This traffic analysis report has been prepared on behalf of the Town of Bay Harbor Islands and serves as a Project Traffic Analysis Report (PTAR) for the improvement of Broad Causeway in Miami-Dade County, Florida, from Bayshore Drive and West Broadview Drive. The report provides the traffic data collection, existing operational analysis, existing safety analysis, traffic forecasting, future operational analysis, and future safety analysis.

The analysis will document existing and future conditions and follow the process outlined in FDOT's *Project Development and Environment (PD&E) Manual*. The results of the PTAR will be prepared and documented as part of the Broad Causeway Bridge Replacement PD&E study. All raw data and supporting information referenced in the analysis will be included with the PTAR deliverable. A traffic analysis methodology, which was approved by the Town of Bay Harbor Islands, is included in **Appendix 7.1**.

### 1.1 Purpose and Need

The purpose of this project is to address the structural and functional deficiencies of the existing Broad Causeway Bridge. The need for the project is to improve bridge deficiencies because the 73-year-old bridge is structurally deficient, functionally obsolete, and contains fracture critical components; improve safety since there have been several vehicular crashes in the project corridor, many involving bicycles and pedestrians that resulted in injuries; improve flow of traffic along the project corridor which has high traffic volumes and frequent bridge openings; and to maintain emergency evacuation.

The feasibility of continued rehabilitation and repair versus replacement of the bridge will be evaluated through the Project Development and Environment (PD&E) study. The need for the project is based on the identified bridge deficiencies provided in the final PER Preliminary Engineering Report.

The purpose of this PTAR is to evaluate the mobility, operations, and safety of Broad Causeway and summarize the travel impacts of proposed typical sections, access changes near the existing Chevron gas station, and proposed Shared Use Path (SUP) along the Broad Causeway. Serving as part of the emergency evacuation route network designated by the Florida Division of Emergency Management (FDEM) and Miami-Dade County, Broad Causeway Bridge plays a critical role in facilitating traffic between the beaches and the mainland of Miami during emergency evacuation periods. Traffic analysis will consider the positive impacts that this project will have on all traffic, including traffic during evacuation.

The traffic analysis process includes:

- Review of existing roadway characteristics
- Collection of recent traffic data
- Analysis of existing year traffic operations and safety performance
- Development of future year traffic volumes
- Analysis of future year traffic operations and safety performance

### 1.2 Project Description

The project involves the potential replacement of the Broad Causeway Bridge connecting the Town of Bay Harbor Islands (Town) with the City of North Miami, within Miami-Dade County. The bridge is part of the Broad Causeway, a roadway classified as “Urban Minor Arterial”. This arterial also begins in Bal Harbour/Surfside and connects those commuters to the mainland. The specific limits of the project extend from the Broad Causeway Island (25°53'19.41"N, 80° 8'54.52"W) on the west side and (25°53'11.30"N, 80° 8'18.93"W) to east of West Broadview Drive. The improvements include the bridge approaches and Broad Causeway Island circulation. The Florida Department of Transportation (FDOT) Bridge Identification (ID) Number (No.) is 875101. A graphic depicting the location of the bridge is provided as **Figure 1-1**. The project is approximately 0.77 mile in length.

The existing bridge consists of four lanes, undivided (two in each direction), the four travel lanes are 10 ft. wide, without a raised median. The outside travel lanes also include shared-use markings to accommodate bicycles. In addition, pedestrians use a raised maintenance area on each side of the bridge, with a width that varies from 22 to 36 inches. There are no guardrails separating the sidewalk from the travel lane. Crossing over the Intracoastal Waterway (ICWW), the bridge has a horizontal clearance of 79.7 ft., a maximum vertical clearance of 18.0 ft. at Mean Low Water (MLW) and a minimum vertical clearance of 15.7 ft. at Mean High Water (MHW) at the Bascule crossing. The ICWW at the bridge crossings is deemed a navigable waterway by the United States Coast Guard (USCG). The bridge bascule is required by the USCG to open twice per hour on the quarter and three-quarter hour but only opens if vessels are waiting.

The existing bridge, constructed in 1951, has been determined to be functionally obsolete with fracture critical components based on a Bridge Inspection Report prepared in January 2023 and determined to be structurally deficient based on a Bridge Inspection Report prepared in January 2024 by FDOT. In 2017, major structural repairs were performed to the bridge at a construction cost of approximately \$17 million. As a result of a 2020 inspection carried out by FDOT, a design to address additional repairs has been completed and it has been determined that the cost to perform these repairs will amount to \$3.0 million. As a result of the 2024 inspection, temporary emergency repairs will be completed. One lane of the bridge is closed until repairs are complete. It is expected that major costly repairs will be needed more frequently as the bridge ages to prevent closure or severe damages. Because of the structure type, the number of structural deficiencies, and high maintenance costs, the Town is considering replacement of the bridge.

This Project Development and Environment (PD&E) Study has been conducted to address the structural and functional deficiencies of the existing Broad Causeway Bridge and to evaluate and compare the feasibility of continued rehabilitation and repair versus replacement of the bridge. The project limits for the PTAR coincide with the limits of the overall project.

The project context classification is not specified since most of the project falls outside FDOT limits. To the west of the project the roadway is classified as C4 Urban General and to the east C5 Urban Center.

There are existing unsignalized movements at the northern and southern Chevron driveways that were analyzed as part of this study.

There are no signalized intersections within the analysis and project limits.

In the preferred alternative the traffic analysis includes multiple stop-controlled intersections and merging and diverging movements between the island developments and causeway mainline.

Additionally, in the preferred alternative there is a mid-block pedestrian crosswalk proposed just east of West Broadview Avenue. For this crosswalk justification and criteria reference the FDOT Traffic Engineering Manual guidance.

Bridge concepts will include provisions for new pedestrian and bicycle accommodations to comply with Americans with Disabilities Act (ADA) requirements and guardrails for the safety of pedestrians.

Existing right-of way (ROW), owned by the Town, is anticipated to accommodate the replacement bridge and approaches. Included in the Town Charter by the 1953 Senate Bill No. 865, the State of Florida surrendered and granted to the Town any claim or control over all tidewaters and other lands, and all bayous and bay bottoms, beaches, waters, waterways and water bottoms, and all riparian rights within and adjacent to the Town limits for municipal purposes only, a strip of 300 ft. wide from Kane Concourse, westwardly across Biscayne Bay to approximately 123rd Street in the City of North Miami. This 300-ft. wide strip is shown in **Figure 1-2** a bright yellow highlight. Therefore, the replacement bridge will be built within the 300 ft. strip over Biscayne Bay under claim or control by the Town.

Figure 1-1 Project Location Map

**Figure 1-2** Depiction of 300-ft. wide strip from Kane Concourse to North Miami

### 1.3 Study Methodology Summary

#### 1.3.1 Study Period

The following years represent the existing year, opening year, and design year for the corridor and intersection performance evaluation.

- Existing Year = 2023
- Opening Year = 2030
- Design Year = 2050

#### 1.3.2 Data Collection

Data is collected within the study limits along Broad Causeway, east of the Chevron Gas station and at intersection locations between the Broad Causeway mainline and Chevron Gas Station. **Figure 1-3** provides a location map of each count location used for the study.

Figure 1-3 Count Location Map

### 1.3.3 Performance Measures

Performance measures for evaluation were selected based on the FDOT policy of target level of service (LOS) for State Highway System arterials in urban areas. The target LOS for intersections and corridors is LOS D.

#### Segments

The operations along study area roadway segments were evaluated based on the following list of performance metrics which are developed using AADT and DHV.

- Travel Time
- Average Speed
- Arterial Level of Service
  - Peak hour analyses using HCM procedures
  - Daily analysis using FDOT's 2023 Generalized Tables based on Context Classification (note: there is no daily analysis option using the HCM process)
- Volume to Capacity Ratio

#### Intersections

To assess the performance of intersections, the subsequent metrics were employed to evaluate each intersection's movement, approach, and overall dynamics during the AM, Mid-day (MID), and PM peak hours.

- Control Delay
- Level of Service
- Volume to Capacity Ratio
- 95th percentile Queue Length

#### Multimodal

The multimodal network performance was evaluated by quantifying the level of traffic stress. The following list of data inputs were reviewed to evaluate the quality of travel for people walking and biking.

- Facility Type
- Lane Width
- Vehicular Posted Speed
- Vehicular Volume
- Separation from Traffic
- Level of Traffic Stress

### 1.3.4 Traffic Analysis Tools

Segment and intersection traffic analysis was completed using operational performance methodologies of the *Highway Capacity Manual, 6th Edition (HCM6)*. For intersections Synchro with HCM was used and for segment analysis HCS7 and Synchro-SimTraffic analysis programs were used. Both of these programs utilize and have the ability to generate the performance measures listed above. Where applicable, HCM reports will be provided for all study intersections.

Multimodal analysis is completed using the FDOT's *2023 Multimodal Quality Level of Service Handbook*. The handbook uses Level of Traffic Stress (LTS) to evaluate the quality of travel for people walking and biking. LTS is segmented into four levels of classification, which vary based on the user type's comfort levels when using the facility.

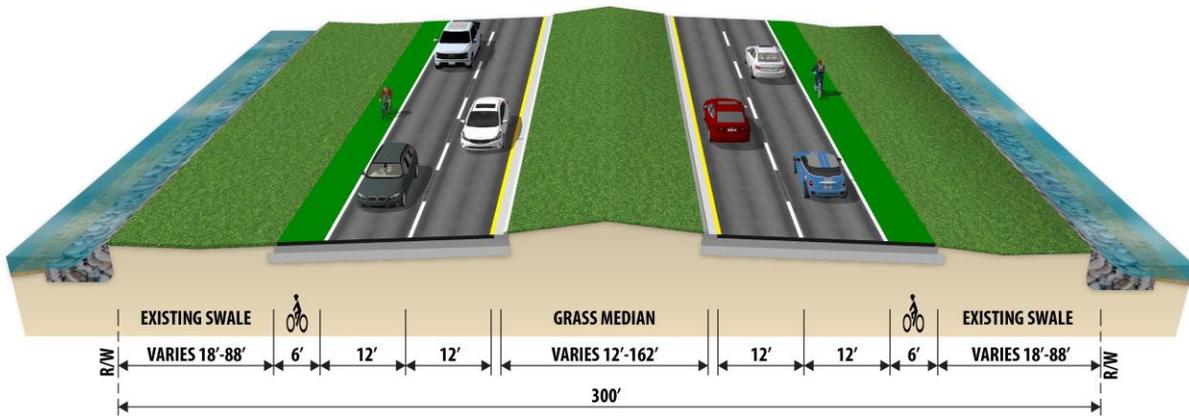

## 2.0 Existing Conditions Analysis

### 2.1 Roadway Typical Sections

There are three existing typical sections within the project limits. The first typical is the existing roadway on the man-made causeway island from Sta. 105+21.37 to Sta. 123+85.28. The typical includes four, 12 ft. travel lanes and 6 ft. shoulders/bike lanes in both directions and no sidewalks. There is a grassed median that varies in width and inside curbs of 2 ft. On the outside of the shoulder there are grassed swales that vary in width and tie to an existing seawall/rip rap. The entire typical fits within the existing ROW owned by the Town (**Figure 2-1**).

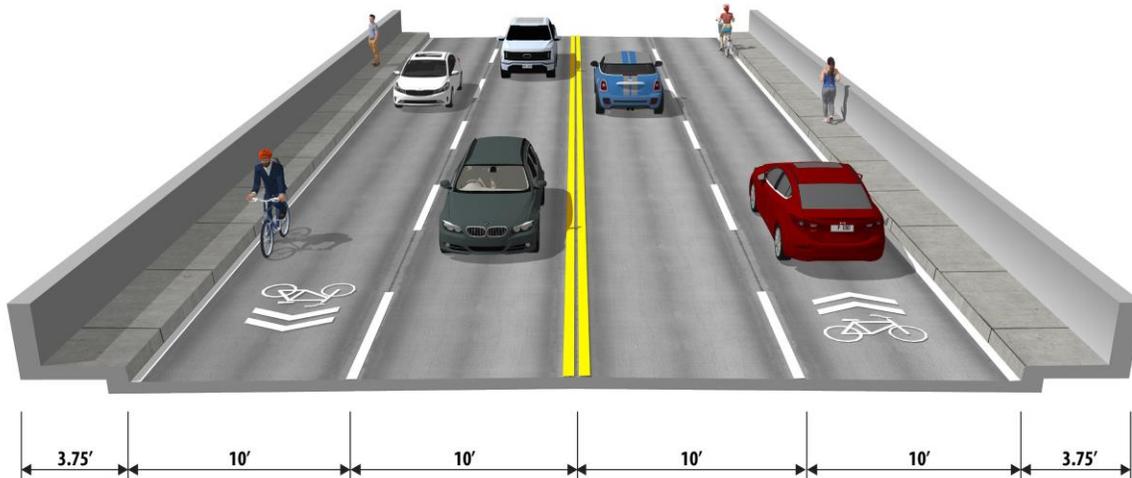

**Figure 2-1 Existing Roadway Typical Section – Causeway Island**

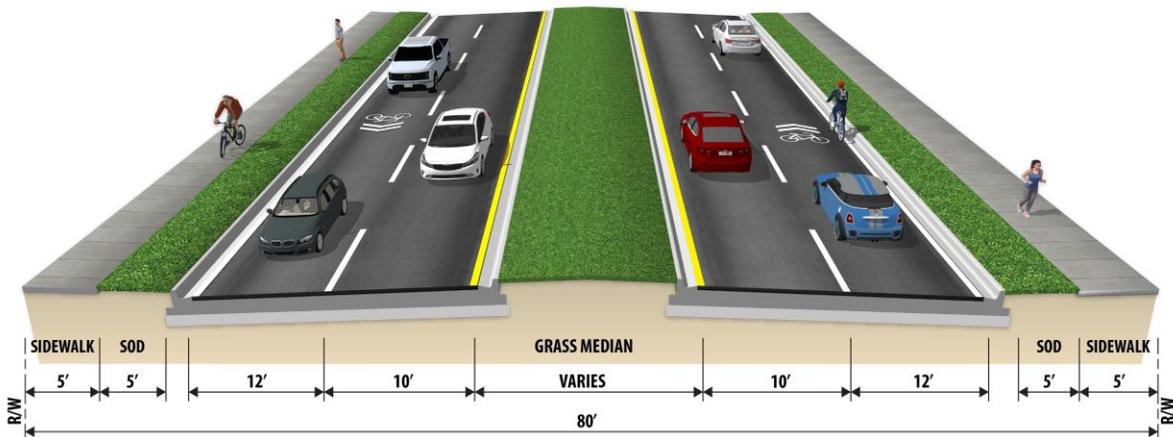

The second typical is the existing bridge with four 10 ft. travel lanes, no shoulders, and a raised 3.75 ft. maintenance section that includes 22 to 36 inches of walkable area and an outside barrier wall. This maintenance section is used as a path for pedestrians and includes a bridge railing. The outside lanes of the existing bridge typical are striped as sharrows for bicycle use (**Figure 2-2**).

**Figure 2-2 Existing Bridge Typical Section**

The third typical is the approach roadway on the eastern end of the existing bridge on SR 922/Kane Concourse from Sta. 141+41.25 to Sta. 146+25.69 and consists of four travel lanes with widths of 10 ft. (inside) and 12 ft. (outside). The typical also includes a landscaped median varying in width and two 2 ft. curbs on both its sides. On the outside are 2 ft. curbs with 5 ft. sidewalks and 5 ft. of existing sod on each side. The outside lanes are striped as sharrows for bicycle use (**Figure 2-3**).

**Figure 2-3 Existing Roadway Typical Section – SR 922/Kane Concourse**

## 2.2 Historical Average Daily Traffic

FDOT’s Florida Traffic Online (FTO) web application was utilized to supplement collected traffic data. Two portable traffic monitoring sites from FTO count information includes historical AADT, directional hourly volumes, vehicle classification, and truck factors. Refer to **Figure 1-3** for location map of each count location used for the study. **Table 2-1** below provides a summary of the FTO count information. FTO Reports are provided in **Appendix 7-4**.

**Table 2-1 Florida Traffic Online Summary**

Count Location (FDOT Site # - Location Proximity)	K Factor	D Factor	T Factor	2022 AADT
878608 – SR 922, 200’ E of Chevron	9.0	56.5	2.6	22,000
871023 – Broad Cswy, 200’ W of Bayshore Dr	9.0	54.7	7.8	24,500

## 2.3 Existing Segment Volumes

Machine counts (7-day, 24-hour) were collected at Broad Causeway for the eastbound and westbound approaches. The counts were used to determine the segment traffic throughout the day and to identify weekday traffic patterns. The counts were conducted by National Data & Surveying Services (NDS) between February 11 and 17, 2023. The counts were evaluated for applicable seasonal adjustments, with the season factor for the corresponding count week being 0.96. A season factor below 1.00 indicates that the data was gathered during the peak season, thus it was decided to not apply a seasonal factor. Peak hours were identified as follows: AM = 8:15-9:15, Mid = 12:15-1:15, and PM = 5:15-6:15.

The weekday and weekend AADT volumes are listed in **Table 2-2**. The raw count data and summarized tube count data are provided in **Appendix 7.2**.

**Table 2-2 Collected Daily Traffic Counts**

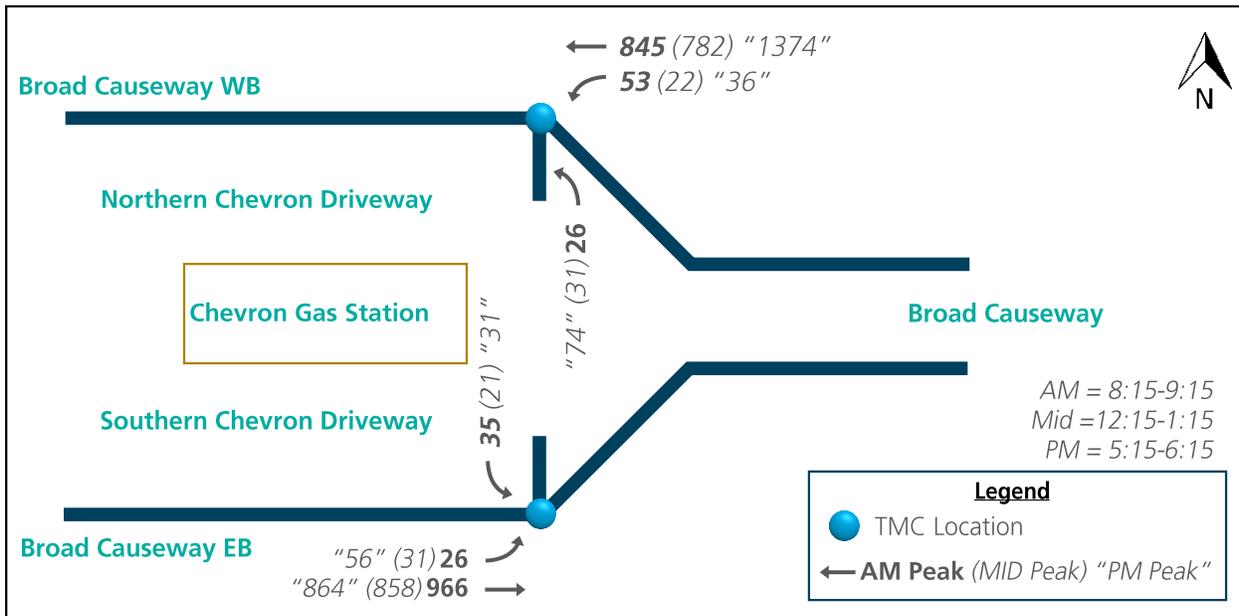

Count Station	Count Location	2023 Weekday AADT	2023 Weekend AADT
1	Broad Causeway, West of Chevron Gas Station	25,100	17,600

## 2.4 Existing Intersection Volumes

Intersection Turning Movement Counts (TMCs) were collected at the study intersection for seven weekday hours by National Data & Surveying Services (NDS) on February 14, 2023. The peak hour turning movement counts are illustrated in **Figure 2-4**. The original TMC reports and TMC summaries used for traffic model input are provided in **Appendix 7.2**. The TMC locations on the TMC diagrams represent combined inbound and outbound movements for both driveways in each approach. The U-turn driveway west of the retail development was not counted as it was negligible based on local knowledge. The only logical users of this U-turn are drivers from the town/beach visiting the gas station and returning back to town. Based on collected westbound inbound trips the U-turn movement is not estimated to be more than 40 vehicles in the peak hour. At this rate it would have no impact on the proposed traffic analysis.

**Figure 2-4 2023 Existing Turning Movement Counts**

## 2.5 Existing Multimodal Volumes

Pedestrians and cyclist travel across the non-bridge portion of the Broad Causeway using the existing green bike lanes provided in both directions. To cross the bridge, bicycles are transitioned to share the vehicular travel lanes and pedestrians elevated curb that serves as a sidewalk.

Pedestrian and bicycle counts were collected at two locations outside of the Chevron Gas Station for twelve weekend hours on Saturday, February 11, 2023, and twelve weekday hours on Tuesday, February 14, 2023, by National Data & Surveying Services. The daily pedestrian and bicyclist counts from the two count locations are listed below in **Table 2-3** and provided in **Appendix 7.2**.

**Table 2-3 Multimodal Traffic Counts**

Date	Time	Type	Eastbound	Westbound
Saturday, February 11 <sup>th</sup> , 2023	7:00 AM – 7:00 PM	Pedestrians	119	122
		Bikes	216	176
Tuesday, February 14 <sup>th</sup> , 2023	7:00 AM – 7:00 PM	Pedestrians	103	95
		Bikes	105	91

## 2.6 Existing Segment Analysis

The 2023 existing condition segment analysis provides a baseline to review no-build and build conditions. The Broad Causeway peak hour segment volumes were obtained from the turning movement counts and daily volumes on the segment were obtained from the 7-day, 24-hour machine counts. Analysis tools included the SimTraffic Arterial Level of Service Reports compared to HCM Urban Street LOS tables for peak hours counts and 2023 FDOT Generalized Service Volume Tables for a reasonableness check of daily volumes.

**Table 2-4** summarizes level of service and volume to capacity for daily using the 2023 FDOT Generalized Service Volume Tables. **Table 2-5** summarizes level of service and travel speed using the SimTraffic Arterial Level of Service Reports and provided in **Appendix 7.5**.

The existing daily segment volumes are compared to the 2023 FDOT Generalized Service Volume Table for a general review of daily operations<sup>1</sup>. This check for reasonableness results in a V/C ratio below 0.69 for daily volumes.

The existing peak hour segment analysis was based on existing travel speed collected from SimTraffic, in which, each peak period and approach exceed 80% of the base free-flow speed. The LOS criteria

<sup>1</sup> The FDOT 2023 Multimodal Quality/Level of Service Handbook serves as a good generalized-planning tool, however it does not provide sufficient detail for project development and environment (PD&E) traffic analysis. The GSVT comparison is provided as a reasonableness check.

from HCM urban street facilities results in a LOS of A for all existing conditions. All existing conditions are within the target of LOS D.

Since the segment analysis is intended to evaluate typical peak hour operations the existing drawbridge interruption to traffic is not included in the segment analysis or models. This is due to the drawbridge operations not occurring on a recurring consistent basis like a traffic signal or stop-controlled intersection would have.

*2.6.1 Simulation Model Validation*

The project limits of this study create a unique analysis conundrum when attempting to use traditional HCM methods. The entire segment speed is posted at 30 mph, which is less than 45 mph minimum speed to be analyzed as a highway. Within the limits of this roughly 0.7-mile segment there are no stop or signal controlled intersections however, to use the HCM method at segment must be bound by a signal or traffic control on the boundaries. For this project there are signals beyond either end of the project limits; of which neither is included in any project improvements. All feasible project alternatives still include the same number of through lanes as in the existing condition. With all these considerations it is proposed that peak hour segment LOS be determined based using SimTraffic travel speeds compared to HCM LOS Travel Speed Threshold Criteria for Urban Street Segments (HCM 6: Exhibit 18-1).

SimTraffic models were calibrated by programming existing posted speeds and input volumes and comparing the model output values for consistency. In the existing PM model, there were 2450 vehicles with a PHF of 0.92, which equates to 2,663 vehicles. The SimTraffic Simulation Summary (provided in **Appendix 7.5.1**) shows that 2,655 vehicles were modeled into the network with 2,643 exiting the network, which represents a model input difference less than 0.5%.

**Table 2-4 Existing Segment Volume Analysis Summary (Daily)**

Roadway	Extents	Scenario	Volume	Service Volume Capacity	v/c	LOS	Targeted LOS
Broad Causeway	Bayshore Dr to West Broadview Dr	2023 Existing	25,100	36,100	0.70	D	D

**Table 2-5 Existing SimTraffic Segment Volume Analysis (Peak Hour)**

Roadway	Extents	Peak Period	Travel Speed (mph)		Level of Service (LOS)		Target LOS
			EB	WB	EB	WB	
Broad Causeway	Bayshore Dr to West Broadview Dr	AM	28	27	A	A	D
		MID	28	28	A	A	D
		PM	28	26	A	A	D

## 2.7 Existing Intersection Analysis

Intersection capacity analysis utilized the Highway Capacity Manual (HCM6) methodology and was completed using Synchro software for the study intersections. Each study intersection includes a yield-controlled traffic movement exiting the Chevron Gas Station. To conservatively model the impacts of the intersections and obtain Synchro HCM6 reports, each intersection was modelled as stop-controlled.

Based on the results from **Table 2-6**, each intersection results in a LOS of C or better.

**Table 2-6 Existing Intersection Volume LOS Analysis Summary**

Intersection	Intersection Control	Peak Period	Approach Delay (LOS)				Intersection Delay (LOS)
			EB	WB	NB	SB	
Broad Cswy & Northern Chevron Dwy	TWSC	AM	--	0.0 (A)	12.3 (B)	--	12.3 (B)
		MID	--	0.0 (A)	11.8 (B)	--	11.8 (B)
		PM	--	0.0 (A)	18.2 (C)	--	18.2 (C)
Broad Cswy & Southern Chevron Dwy	TWSC	AM	0.0 (A)	--	--	13.0 (B)	13.0 (B)
		MID	0.0 (A)	--	--	12.0 (B)	12.0 (B)
		PM	0.0 (A)	--	--	12.6 (B)	12.6 (B)

## 2.8 Existing Multimodal Analysis

The existing multimodal operations were assessed by using the Level of Traffic Stress (LTS) metric. LTS is an approach developed by the Mineta Transportation Institute that focuses on classifying the comfort pedestrians and bicyclists experience while using a roadway. The practice has been adopted by FDOT to quantify the impacts of a facilities features have on multimodal users' comfort levels. Roadways were assigned a stress level of one to four with LTS 1 signifying very low stress and LTS 4 signifying high stress.

Determining LTS for a facility is based on a variety of factors and conditions, such as the presence and configuration of dedicated or mixed traffic facilities.

The criteria for determining the LTS for the facility encompassed inventory of dedicated continuous sidewalks proportion, posted speed limit, horizontal separation, and vertical separation. Since there is no sidewalk present along the Broad Causeway Island, the LTS for pedestrians was Level of Traffic Stress 4. This facility would feel uncomfortable for most users traveling without a bicycle since only a bike lane is present.

The evaluation criteria used to analyze bicyclist were type of bicycle facility, posted speed limit, AADT, on-street parking, and width of bicycle lane. After reviewing each roadway characteristic, the level of traffic stress for a pedestrian and bicyclist crossing the bridge was LTS 4 (which is defined as a route that is impassable by a wheeled mobility device or represents a level tolerated only by those with limited route choice or tolerated by a cycling enthusiast).

### 3.0 Existing Traffic Safety Analysis

#### 3.1 Historical Crash Summary

A historical safety review was conducted within the study limits using five years of available crash records occurring between January 1, 2018 and December 31, 2022. Crash data and crash reports were obtained from the Signal Four Analytics (Signal4) database and reviewed in accordance with FDOT Safety Crash Data Guidance. The Signal4 database uses crash records obtained from the FLHSMV crash records and is maintained by the GeoPlan Center at the University of Florida.

Detailed crash data, including crash type, crash severity, lighting conditions, roadway surface conditions, etc., was reviewed and summarized in text, tabular, and graphical forms to convey critical trends experienced in the historical cash data. For safety analysis purposes, the study area includes crashes occurring within 250-feet of intersections in the project limits.

Within the study limits a total of 47 crashes were reported over the five-year period. A summary of the crash analysis is provided in this section. A heat map of the crash locations can be found below in **Figure 3-1**.

Figure 3-1 Heat Map of All Crashes

### 3.2 Crash Type and Severity

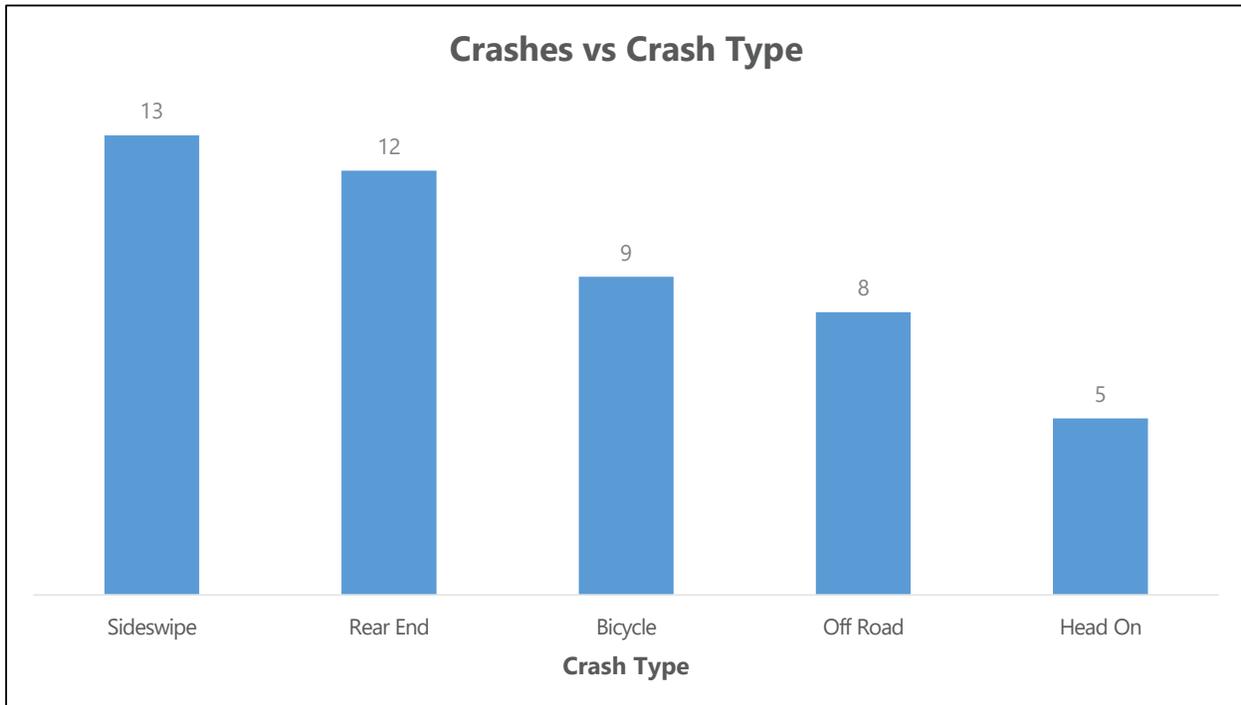

Crash data was reviewed to record the severity of crashes and contributing factors. Of the 47 crashes, 2 resulted in serious injury, 18 resulted in injury, and 27 resulted in property damage only.

In the five-year crash history, there were 13 sideswipe crashes, which accounted for 28% of the total crashes. The next most common crashes were rear-end crashes (12) and bicycle crashes (9).

**Table 3-1 Crash Type by Level of Severity**

Crash Type	Severity				Grand Total
	No Injury	Possible Injury	Non-Incapacitating Injury	Incapacitating Injury	
Sideswipe	13				13
Rear End	6	4	2		12
Off Road	6	2			8
Bicycle			8	1	9
Head On	2	1	1	1	5
<b>Grand Total</b>	<b>27</b>	<b>7</b>	<b>11</b>	<b>2</b>	<b>47</b>

**Figure 3-2 Crash Type Frequency**

### 3.3 Detailed Serious Injury Crash Review

Within the study period, two crashes resulted in incapacitating injuries. This section provides a contextual summary of those crashes which provided additional insight for recommending crash countermeasures and safety design improvements.

- In September 2018 at approximately 7:30 AM, vehicle 1 was traveling eastbound on the Broad Causeway Bridge just east of the Chevron gas station. Vehicle 1 entered the inner westbound travel lane striking vehicle 2 head-on which resulted in serious injuries for the driver of vehicle 2.
- In February 2020 at approximately 7:00 AM during clear and dry weather conditions, a bicyclist traveling eastbound on Broad Causeway Bridge/SR 922 near W Broadview Drive rear-ended by a vehicle also traveling eastbound. The bicyclist sustained incapacitating injuries.

### 3.4 Detailed Bicycle and Pedestrian Crashes

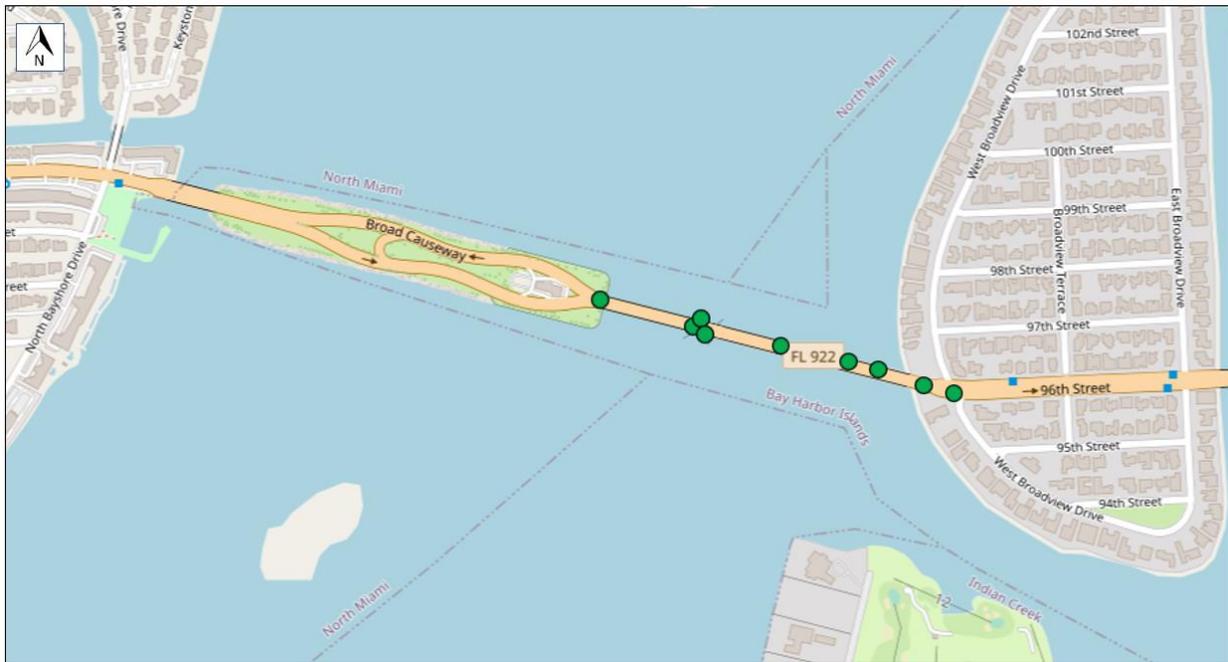

Of the total crashes, nine reported crashes involved bicycles and resulted with injuries. There were no reported pedestrian crashes. The location of the bicycle crashes are shown in **Figure 3-3**. A detailed summary of each bicycle crash is provided below:

- In February 2020 at approximately 7:00 AM, a bicyclist traveling eastbound on Broad Causeway Bridge/SR 922 near W Broadview Drive was struck from behind by a vehicle also traveling eastbound. The bicyclist sustained incapacitating injuries. At the time of the crash the weather was clear and pavement was dry.
- In March 2020 at approximately 11:00 PM, a bicyclist was traveling eastbound on Broad Causeway Bridge when a vehicle collided into the bicyclist with the right-side view mirror. The bicycle was totaled in the crash. The crash occurred during nighttime with poor lighting conditions.
- In August 2020 at approximately 1:05 PM, a push scooter that had been upgraded with a motor lost control of the scooter while crossing the metal grate. The scooter was traveling eastbound and had to use maximum speed to travel up the bridge. The pavement was wet.
- In October 2020 at approximately 3:13 PM, a motorist utilizing a motor scooter adjusted his sideview mirror resulting in him losing control of the motor scooter and falling onto the roadway. Weather conditions were clear and the pavement was dry.
- In March 2021 at approximately 9:45 PM, a vehicle traveling eastbound rear ended a bicyclist. The side view mirror of the vehicle also struck the bicycle and bicyclist. The crash occurred during nighttime with poor lighting conditions.
- In October 2021 at approximately 9:27 PM, a vehicle traveling westbound on the Broad Causeway Bridge struck a non-motorized scooter. The crash occurred during nighttime with poor lighting conditions.
- In February 2022 at approximately 2:00 PM, a vehicle traveling eastbound struck a bicyclist traveling eastbound. Weather conditions were clear and the pavement was dry.

- In April 2022 at approximately 11:00 PM, a motorist utilizing a scooter was travelling westbound on the Broad Causeway Bridge and slid on the metal grating causing the driver to fall off of the scooter. The crash occurred during nighttime with cloudy weather conditions and wet pavement.
- In May 2022 at approximately 7:18 PM, a motorcyclist was travelling westbound on the Broad Causeway Bridge and lost control of the vehicle causing the driver to fall over on their left side. The weather was clear and the pavement was dry.

**Figure 3-3 Bicycle Crash Map**

Legend: Map points represent approximate locations of bicycle crashes.

### 3.5 Temporal Crash Trends

Crash data and reports were assessed to determine temporal trends in the statistics. This review included crash year, month, day of the week, and time-of-day.

The five-year historical crash trends peaked in 2020 and remained consistent throughout 2022 with 11 or 12 crashes each year, as seen in **Figure 3-4**.

Friday was the most common day for crash occurrences with 11 crashes, as seen in **Figure 3-5**. Tuesday had the second highest crash occurrence with 10 crashes. The average per weekday count was 8 crashes. There is a decrease in crashes over the weekend which aligns with a typical school and work week.

For time-of-day analysis, the crash frequency was highest during the 2 PM hour with 6 crashes as seen in **Figure 3-6**. There is a secondary peak at the 11 AM and the 5 PM hour with 5 crashes. Overall, the hourly crash trends correlate with typical fluctuations in traffic volumes observed throughout the day.

**Figure 3-4 Crashes per Year**

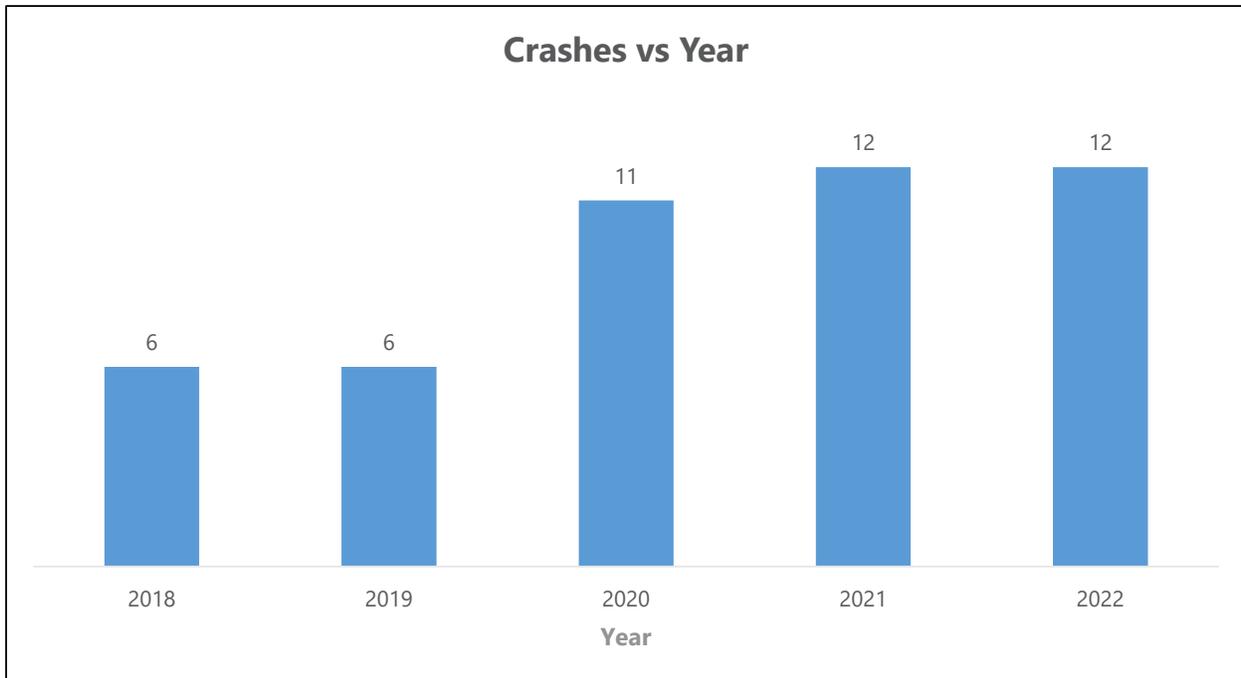

Figure 3-5 Crashes per Day of the Week

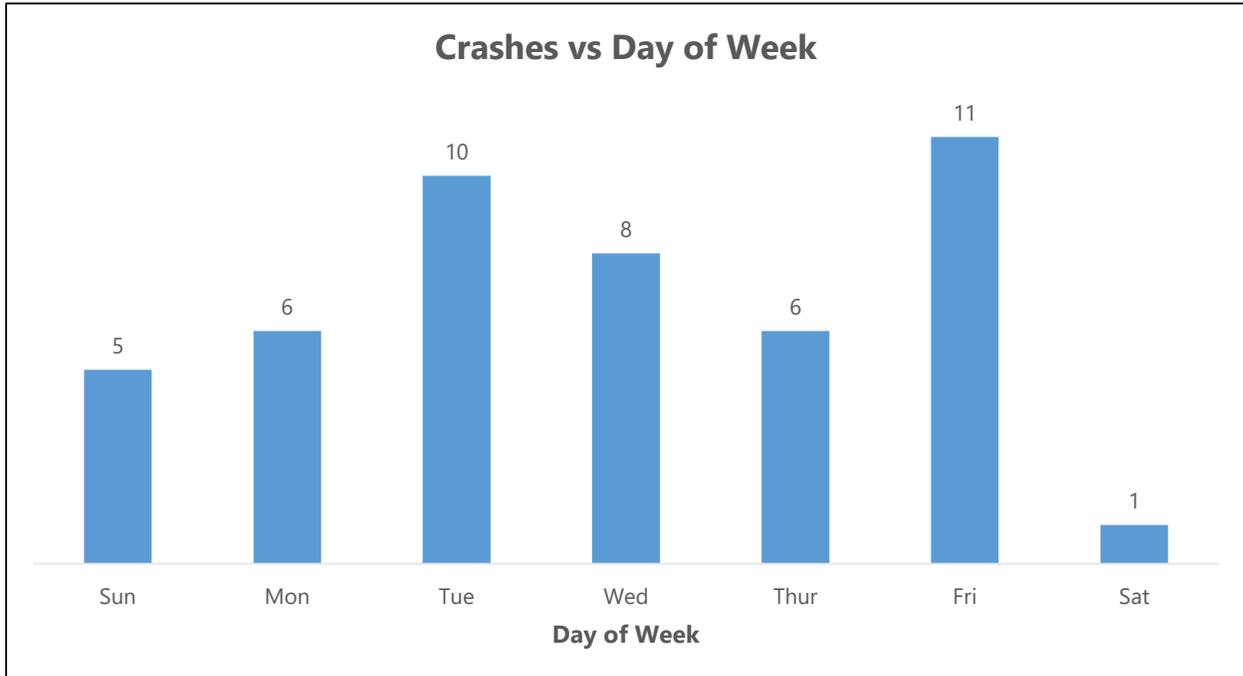

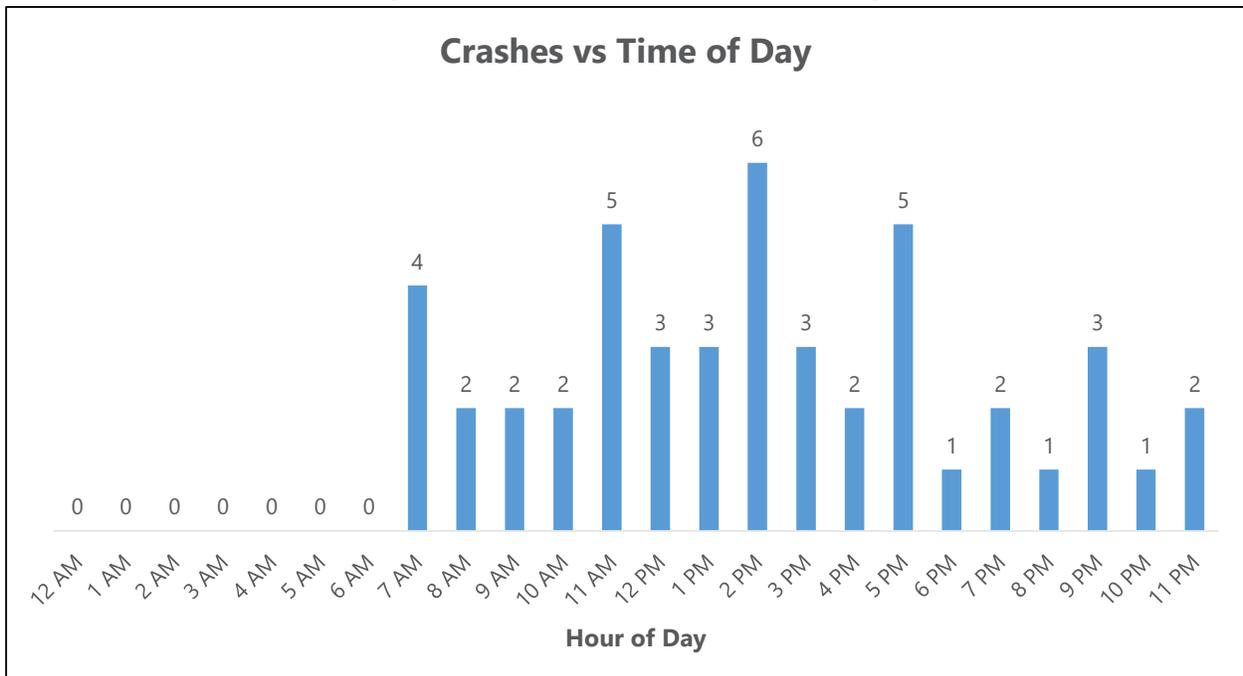

Figure 3-6 Crashes per Time of Day

### 3.6 Crash Condition Trends

#### Weather Conditions

Crash data records the prevailing weather conditions at the time of crash occurrence. The majority of the crashes within the study area occurred during clear weather conditions (90%), as seen in **Figure 3-7**. The remaining crashes occurred in cloudy (8%) or rain (2%) weather conditions.

#### Light Conditions

Crash data includes the prevailing lighting condition estimated at the time of the crash. The majority of crashes occurred during daylight conditions (80%) as summarized in **Figure 3-8**. The remaining crashes (20%) occurred during “dark-lighted” conditions.

#### Road Surface Conditions

Approximately 90% of the total crashes occurred during dry road surface conditions as seen in **Figure 3-9**. The remaining 10% of the crashes occurred during wet surface conditions.

**Figure 3-7 Weather Condition at Time of Crash**

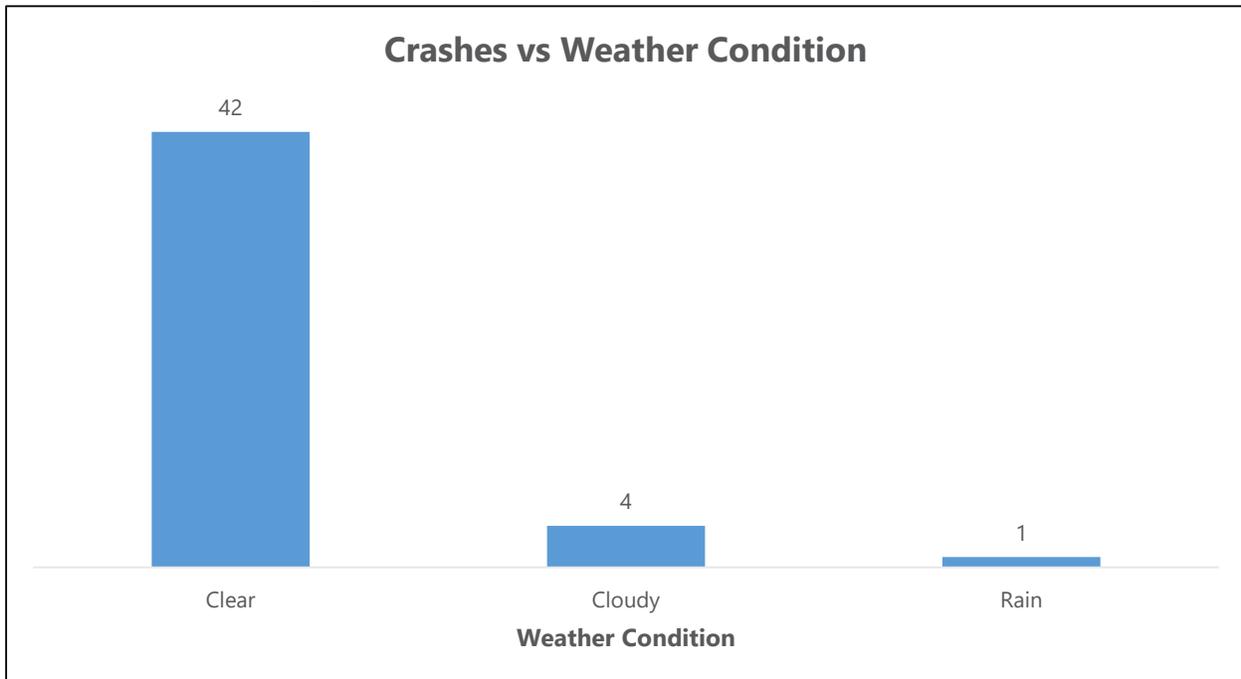

Figure 3-8 Lighting Condition at time of Crash

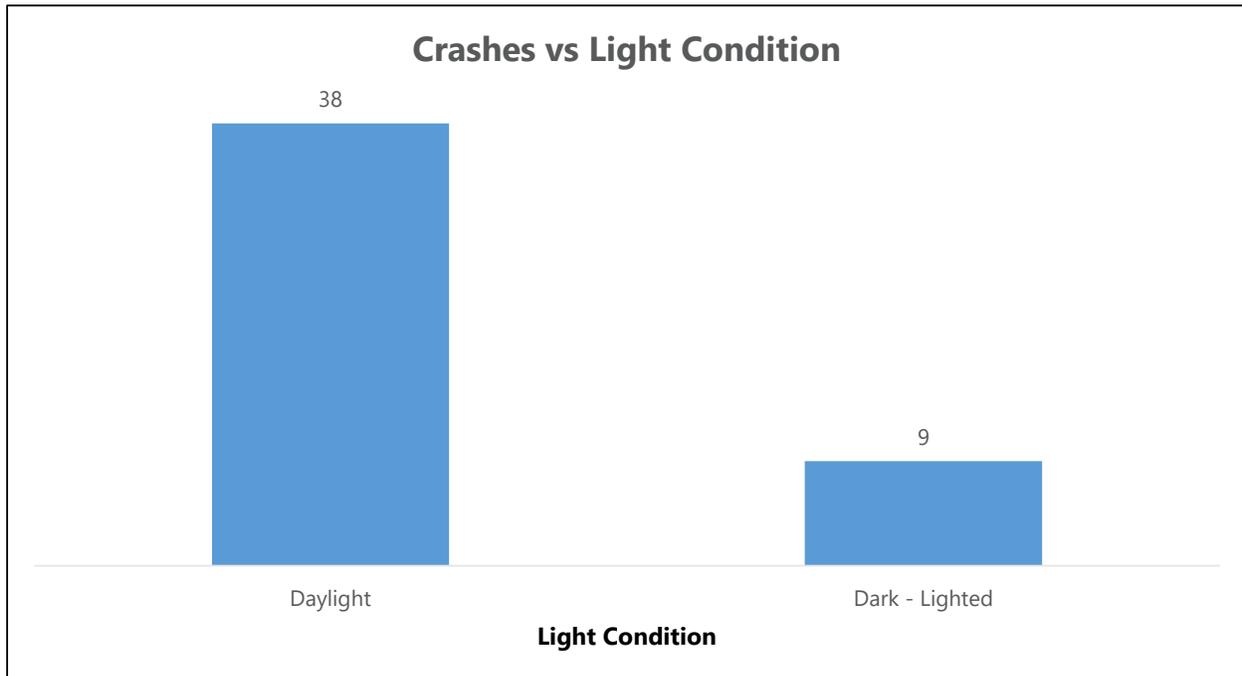

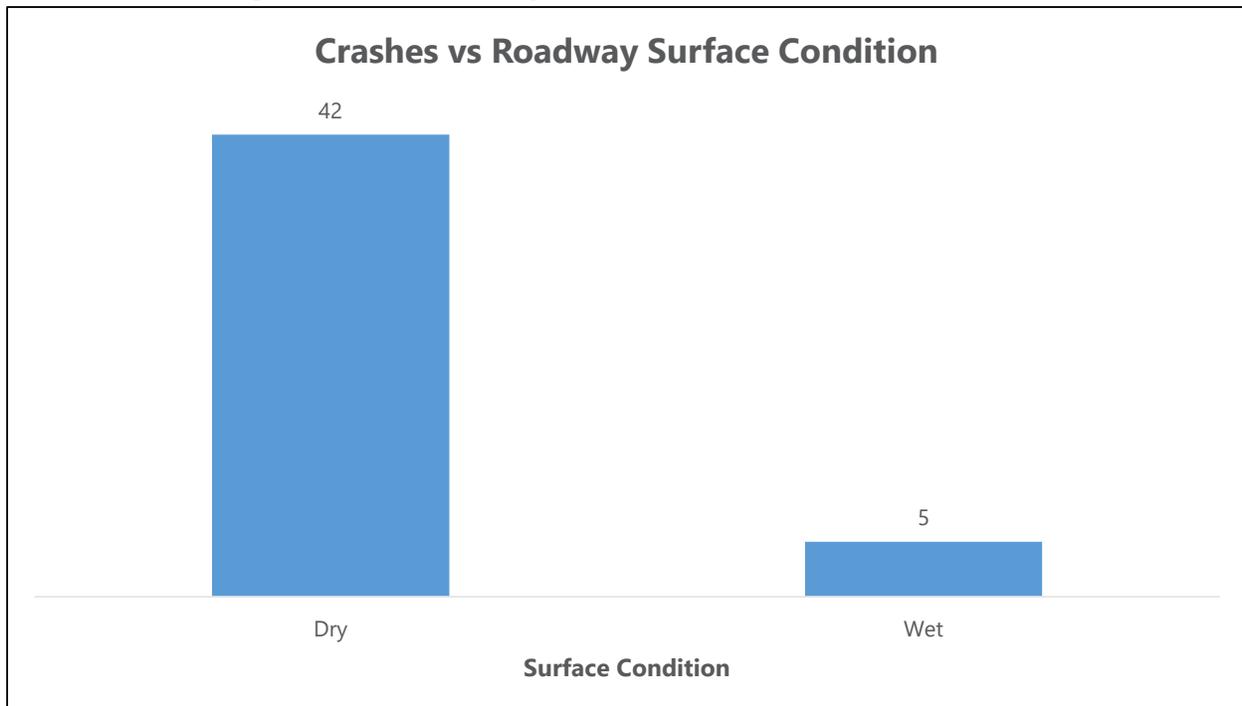

Figure 3-9 Roadway Surface Condition at time of Crash

### 3.7 Segment Crash Rates

Crash rates for the study corridor were calculated for the entire project limits. The segment was analyzed from 250-feet east of North Bayshore Drive to 500 feet west of East Broadview Drive.

The context classification of the town maintained Broad Causeway is not specified since most of the project falls outside FDOT of limits. To the west of the project the roadway is classified as C4 Urban General and to the east C5 Urban Center. For safety analysis purposes and to compare study area to the statewide average crash rates Broad Causeway is identified as an urban, four-lane, roadway with either raised divided or undivided medians. The study area was then broken up into 3 segments based on the roadway median type. A map displaying the roadway segment classifications can be found in **Figure 3-10**. Crash rates per million vehicle miles traveled (MVMT) were calculated for each year from 2018 through 2022 for the study area.

The number of crashes along the segment, the associated crash rate based on crashes per million vehicle miles traveled, and the statewide average for similar facilities for years 2018 through 2022 are summarized in **Table 3-2** below. At the time of this report, 2020 through 2022 statewide average crash rates for segment analysis were not available. The 5-year average crash rate (2018-2022) for the divided and undivided roadway segments were below the 2016-2019 statewide average crash rates.

**Figure 3-10 Segment Classification for Safety Analysis**

**Table 3-2 Historical Crash Rates**

Context & Median Type	Limits	Mile Post		Metric	Year					Average
		Begin	End		2018	2019	2020	2021	2022	
Urban General (C4) Divided Raised	250-ft E of N Bayshore Dr to East of gas station access	3.764	4.216	AADT	21,000	21,000	22,000	21,000	22,000	
				Crashes	2	2	2	3	3	
				Crash Rate	0.58	0.58	.055	0.87	0.83	0.68
				Statewide avg Crash Rate	3.92	3.89				3.88
Urban Center (C4) Undivided	E of gas station access to east shore of bridge	4.216	4.566	Crashes	3	4	6	8	5	
				Crash Rate	1.12	1.49	2.14	2.98	1.78	1.90
				Statewide avg Crash Rate	7.31	7.34				7.30
Urban Center (C4) Divided Raised	East shore of bridge to 500 ft west of E Broadview Dr	4.566	4.736	Crashes	1	0	3	1	4	
				Crash Rate	0.77	0	2.20	0.77	2.93	1.36
				Statewide avg Crash Rate	3.92	3.89				3.88

Roadway ID: 87066000, Note: AADT from FTO site 878608. Crash Rates shown in crashes per 100 million vehicles miles of travel.

### 3.8 Crash Analysis Summary

In summary, over the five-year analysis period from 2018 to 2022, the study area exhibited a majority of the crashes to be sideswipe crashes (28%) and rear end crashes (26%). The high occurrence of rear-end and sideswipe crashes occurred on the approaches to the bridge (segment 2) and may be related to stopping conditions caused by drawbridge interruptions to traffic. Monthly, weekly, and hourly crash trends observed based reflect that which would be expected due to the neighboring schools and commerce patterns. The Historical Crash Rate analysis indicates that all three segments of the corridor are experiencing fewer crash frequencies the statewide average. A crash summary is provided in **Appendix 7.3**.

## 4.0 Development of Traffic Forecast

### 4.1 Traffic Forecasting Methodology

The Southeast Florida Regional Planning Model (SERPM), turning movement counts, and 24-hour machine counts collected in the field were used to forecast future year volumes for this study.

Future traffic was developed using the growth rate derived from travel demand forecasting, historical growth rates and population projections to forecast a future year (2050) design volume based on the existing volume estimates.

The steps used in developing the growth rate are listed below:

1. Growth rates were obtained from the Southeast Florida Regional Planning Model
2. Historical AADT volumes were obtained to review historical traffic trends
3. Population projections from the Florida Department of Transportation (FDOT) were obtained to understand the population growth in the study area
4. Population projections from the Bureau of Business and Economic Research (BEBR) were obtained as an additional resource to understand the future growth in the study area
5. Based on all the above information, a growth rate was determined and recommended for use in future traffic projections
6. The Opening (2030) and Design (2050) Year segment and intersection volumes were generated by applying the selected annual average growth rate to Existing Year 2023 traffic volumes

To determine an average growth rate, each step of the traffic forecasting methodology was considered.

### 4.2 Demand Model

Travel Demand Forecasting analysis was incorporated into the PTAR to develop future-year design traffic volumes. The Southeast Florida Regional Planning Model (SERPM) Version 8.524 was utilized in the development of future travel demand. The SERPM has a base year of 2015 and a horizon year of 2045 and projects traffic by assumed growth rates and adding constructed and committed roadway improvements. Between 2015 and 2045 years the demand model represents a 0.29% annual growth rate in traffic volumes. Model outputs are provided in **Appendix 7-4**.

To validate the appropriateness of the model, actual 2015 AADT volumes and 2015 base year model volumes were compared to evaluate the model's ability to reasonably replicate actual traffic volumes.

The SERPM 2015 Total Daily two-way volume was reported as 29,235. Florida Traffic Online Count site 878608, which is located within the study limits, reported the AADT for this segment to be 19,300. According to the *FDOT FSUTMS-Model Calibration and Validation Standards* the acceptable percent error between a demand model and actual counts for 4-lane facilities between 10,000 and 30,000 vehicles per day is 30% (20% preferred). Given the 2015 actual counts were 50% lower than the model estimated values, it's determined that the model unreasonably overestimates volumes along the Broad Causeway. Even though the model volumes are not reasonable, the annual growth rate is shown in this analysis as a possible tool to compare growth rates against.

### 4.3 Historical Growth

Historical AADT counts published on FDOT's Florida Traffic Online were referenced to determine a growth rate that reflects how traffic has changed in recent years. **Table 4-1** illustrates historical AADT and growth rates. The AADT counts are provided in **Appendix 7-4**.

**Table 4-1 Historical AADT Counts**

Year	AADT	AADT
	<i>Broad Causeway, Site 878608, 200' East of Gas Station Access</i>	<i>Broad Causeway, Site 871023, 200' West of Bayshore Drive</i>
2022	22,000	24,500
2021	21,000	23,000
2020	22,000	21,500
2019	21,000	23,500
2018	21,000	22,000
2017	24,000	22,500
2016	24,000	24,000
2015	19,300	25,000
2014	19,500	23,000
2013	19,700	24,000

#### 4.4 Regression Analysis Using Historical Traffic Data

The FDOT Trends Analysis Tool was used to estimate future growth rates. The growth trends that occurred between 2013 and 2022 were assumed to be representative of future growth to forecast traffic for the year 2030 and 2050.

When performing regression analysis, there are multiple ‘best-fit’ lines used to determine a growth rate for traffic. The types of growth used for this analysis were linear growth and decaying exponential growth. Each growth is explained briefly below:

- Linear growth is a method that assumes a constant amount of growth each year and does not consider a capacity restraint.
- Decaying exponential growth is a method used in mature areas when build-out is approaching.

**Table 4-2** represents the linear and decaying exponential growth percentages for the nearby count stations. Trend’s worksheets and graphs documenting this analysis are provided in **Appendix 7-4**

**Table 4-2 Regression Analysis Summary**

<i>FDOT Trends Growth Type</i>	<i>Broad Causeway, 200’ East of Gas Station Access</i>	<i>Broad Causeway, 125; West of Bayshore Drive</i>
<i>Linear</i>	0.90%	-0.44%
<i>Decaying Exponential</i>	0.22%	-0.10%

## 4.5 Populations Projections

In the FDOT Project Traffic Forecasting Handbook, there are two supported resources for projecting population: (1) the Bureau of Economic and Business Research (BEBR) and (2) the FDOT Forecasting and Trends Office. BEBR provides population forecasts to 2050 in five-year increments on its Demographic Analysis Website. The BEBR projections supply a low, medium, and high forecast while the FDOT publishes one population projection by county and district. The population projection summary for Miami-Dade County from the BEBR data and the Florida Department of Transportation (FDOT) is provided in **Table 4-3** and **Table 4-4**.

Population data sources are provided in **Appendix 7.4**.

**Table 4-3 BEBR Population Projections Summary**

Population Projections Tool	Range	2025	2050	Annual Rate
The Bureau of Economic and Business Research (BEBR)	Low	2,685,500	2,549,500	-0.20%
	Medium	2,826,900	3,186,900	0.51%
	High	2,968,200	3,824,300	1.15%

**Table 4-4 FDOT Population Projections Summary**

Population Projections Tool	2020	2050	Annual Rate
FDOT	2,849,900	3,714,000	1.01%

## 4.6 Recommended Annual Model Volume Growth Rates

After reviewing the study area's historical growth trends and population projections, it is determined that all growth rate estimates fell between an annual range of -0.57% and 1.01%.

Taking into consideration each data estimate, the recommended annual growth rate for use in developing future volumes is 1.00% per year linear growth rate, as presented in **Table 4-5**.

**Table 4-5 Annual Growth Rate Summary and Recommendations**

Facility	Count Location	Linear Growth	Decaying Exponential Growth	SERPM <sub>2</sub>	BEBR Projection	FDOT Projection	Suggested Annual Growth
Broad Cswy	E of Gas Station	0.90%	0.22%	0.29%	0.51%	1.01%	<u>1.00%</u>
Broad Cswy	W of Bayshore Dr	-0.44%	-0.57%				

2 SERPM outputs were not validated for this project corridor. Given the model's significant overestimation of volume, caution should be used when considering growth rates generated by the model. Model growth rates are shown for comparison purposes.

## 5.0 Future Conditions Analysis

Future conditions analysis represents evaluation of the study area performance metrics for the Opening and Design years for the existing, no-build, and alternative build configurations. The future condition traffic analysis is based on growing the existing volumes by the recommended annual 1.0% growth rate. The same performance measures used in the existing analysis, **Section 2.5**, were also used to analyze the Opening and Design year for both No-Build and Build scenarios. The Broad Causeway mainline no-build and build volumes are assumed to be the same in both analysis scenarios. The Build scenario alternatives include opening and design year build alternatives. The objective of the build alternatives was to evaluate the mobility, operations, and safety impacts of the Broad Causeway improvements.

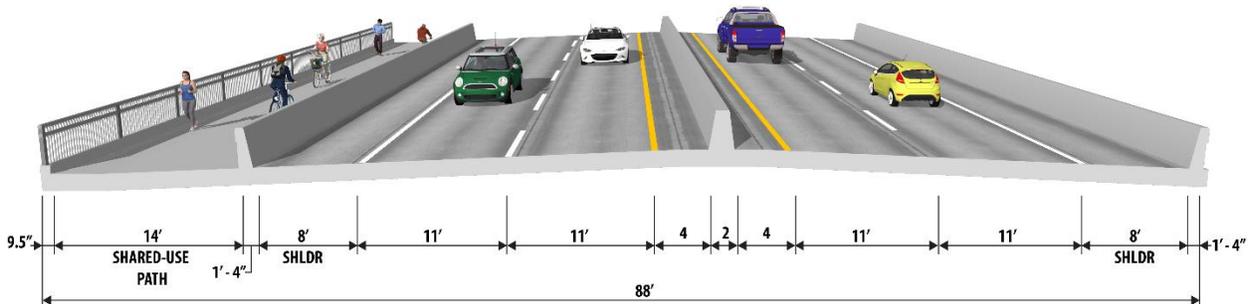

### 5.1 Alternative Design Concepts

The Preliminary Engineering Report (PER) for this same project has identified a preferred alternative, which will be used for future build year analysis in the following sections. For organizational purposes, the design alternatives are separated between bridge typical section changes and Causeway Island circulation changes.

#### Bridge Typical Section

A four-lane divided roadway typical section was developed for the project. This typical section consists of two 11-foot lanes in each direction separated by 4-foot, inside shoulders and a 2-foot, concrete barrier wall. The outside shoulders are 8-foot and are adjacent to concrete barrier walls, and a 14-foot shared use path is proposed along the north side of the bridge with a 42-inch-high pedestrian/bicycle railing. The proposed bridge typical section is shown in **Figure 5-1**. The Design speed for all proposed typical sections is 30 mph, maintaining the existing posted speed of 30 mph. Additionally, the PER identifies the preferred alternative for the bridge deck is a 65-foot High-Level Fixed-Bridge with no drawbridge.

**Figure 5-1 Example of Bridge Typical Section Alternative**

#### 65 ft. High-Level Fixed Bridge Alternative Typical Section

**Causeway Island Vehicular Circulation plans:**

The PER identified a preferred concept that proposes modifications to the causeway island that includes new access ramps to and from the existing service station.

This concept also includes two-way ingress/egress to the existing service station, provides safer pedestrian facilities (no pedestrian crossings on causeway island), and circulation within the causeway island proposed under the mainline (providing even more greenspace). The new movements and revised access to the Chevron gas station are illustrated in **Figure 5-2**.

From an intersection perspective, the build alternative changes how vehicles enter and exit the Chevron gas station. The new vehicle interactions include locations where traffic merge and diverge with the proposed frontage road ramps and stopped controlled intersections from the gas station driveways and frontage roads. A description of operational changes for entering and existing the gas station is provided below:

- Entering Chevron development: Vehicles accessing the development from the west diverge onto a deceleration lane approximately 300' after entering the island. These vehicles remain on a one-lane, one-way roadway on the south side of the island until reaching the development on the east side of the island. Vehicles accessing the development from the east diverge onto a deceleration lane approximately 550' after entering the island. These vehicles combine with the exiting vehicles from Chevron. They then diverge southbound underneath Broad Causeway to the stopped controlled intersection that combines them with the entering vehicles from the west.
- Exiting Chevron development: Vehicles exiting west travel on a one-lane, one-way roadway on the north side of the island. Approximately 300' from the east side of the island these vehicles merge with the mainline westbound through vehicles. Vehicles exiting east initially travel on the same roadway as the westbound exiting vehicles before diverging onto a one-lane one-way road traveling underneath Broad Causeway. After reaching the south side of the island, this roadway intersects with the eastbound frontage road at a stopped controlled intersection. After completing a southbound left-turn, vehicles then merge onto Broad Causeway using a 350' acceleration lane.

Figure 5-2 Causeway Island Circulation Concept

### Project Limits and State Road Tie-ins

The project ties into state-maintained facilities on either end with the same 4-lane typical section to match the existing condition. The specific limits of the project extend from the Broad Causeway Island (25°53'19.41 "N, 80° 8'54.52 "W) on the west side, which is just east of the existing cashless tolling location, and 25°53'11.30"N, 80° 8'18.93"W), which is just east of West Broadview Drive.

- Western Project Limit Tie In

East of the western project limit there is a new proposed westbound merge and eastbound diverge to and from the median access, however there are no anticipated transportation impacts. Merge and diverge analysis are provided in the sub-subsequent sections.

- Eastern Project Limit Tie In

At the eastern project limit tie in there are no geometric concerns as the typical section will match existing typical sections. The bridge vertical will match existing grade at a location close to where the existing bridge does. The PER states the preferred alternative alignment is proposed adjacent to the existing bridge and is offset from the existing alignment to the south by approximately 85 ft. at the ICWW. The horizontal geometry will utilize the Town's empty lot on the east end of the project and stay on the south side of the causeway island to provide ample greenspace for optional recreational space. The key component of the vertical geometry is clearing the ICWW by the USCG required 65 ft. and staying above the existing service station. To achieve this the proposed design will utilize roadway slopes of 5.78% east of the ICWW and 4.95% west of the ICWW. Proposed horizontal and vertical geometry is shown in detail on the concept plans in the PER. A graphic of the layout is provided in **Figure 5-3**.

## Mid-block Pedestrian Crosswalk

To provide complete connectivity for pedestrians a midblock crossing is proposed in the Preferred Alternative to be located just east of West Broadview Drive at Station 144+80 (**Figure 5-3** and **Figure 5-4**). The midblock crossing will connect pedestrians to the south sidewalk east of the project and will include warning signs and other special emphasis features to alert drivers of the upcoming crossing. During design the mid-block crossing will be further analyzed to determine what the safest and most efficient option will be for pedestrian and bicycle crossing. The conceptual design options include special emphasis crosswalk pavement markings at the proposed crossing location. Wayfinding signs will be included to direct pedestrian and bicycle movement in the vicinity of the bridge.

- Mid-Block Crosswalk Justification:

The current version of the FDOT Traffic Engineering Manual (TEM) Section 5.2 establishes criteria and guidelines for the consistent installation and operation of pedestrian treatments at midblock and unsignalized intersections on the State Highway System. These TEM criteria were referenced to facilitate decisions related the crosswalk proximity to generators and section of appropriate traffic control.

The crosswalk meets the TEM strategic plan and validation criteria for placement of marked crosswalks at midblock locations (TEM 5.2.5.1). The crosswalk will connect pedestrians on the south side of SR 922 to the sidewalk connecting to the shared use path across the Broad Causeway. The context classification at this location is C4-Urban General, for which the TEM states does not require a minimum pedestrian volume threshold.

- Mid-Block Crosswalk Control Type Selection:

The crosswalk location shown in the concept figures was chosen to accommodate two considerations; to avoid crossing within the eastbound turn lane at E. Broadview Drive and to maximize the distance between the crossing and the bridge vertical curve.

Based on TEM 5.2.5.2 the crosswalk location meets criteria for an RRFB application. This location has a posted speed below 35 mph and cross-section is four through lanes with a refuge island in the median. Due to the proximity of this crosswalk location to the bridge design could consider In-Roadway Warning Lights to enhance the crosswalk awareness.

With this crosswalk location approximated at 300-400 feet east of the proposed new alignment of the Broad Causeway Bridge vertical curve there is concern that a higher emphasis crossing control, such as a midblock traffic control, would be more appropriate. Because the context classification of this location is C4-Urban General this control type can be accommodated without need to meet Warrant 4 of the MUTCD. Additionally, there is not currently a pedestrian crossing here, so it is unexpected to achieve minimum pedestrian crossing volumes until a crossing is installed.

In the design phase of this project all safety and design considerations with respect to stopping sight distances, illumination levels, and corresponding signing, marking, and signal treatments will be designed and documented.

Figure 5-3 Eastern Project Limits Concept

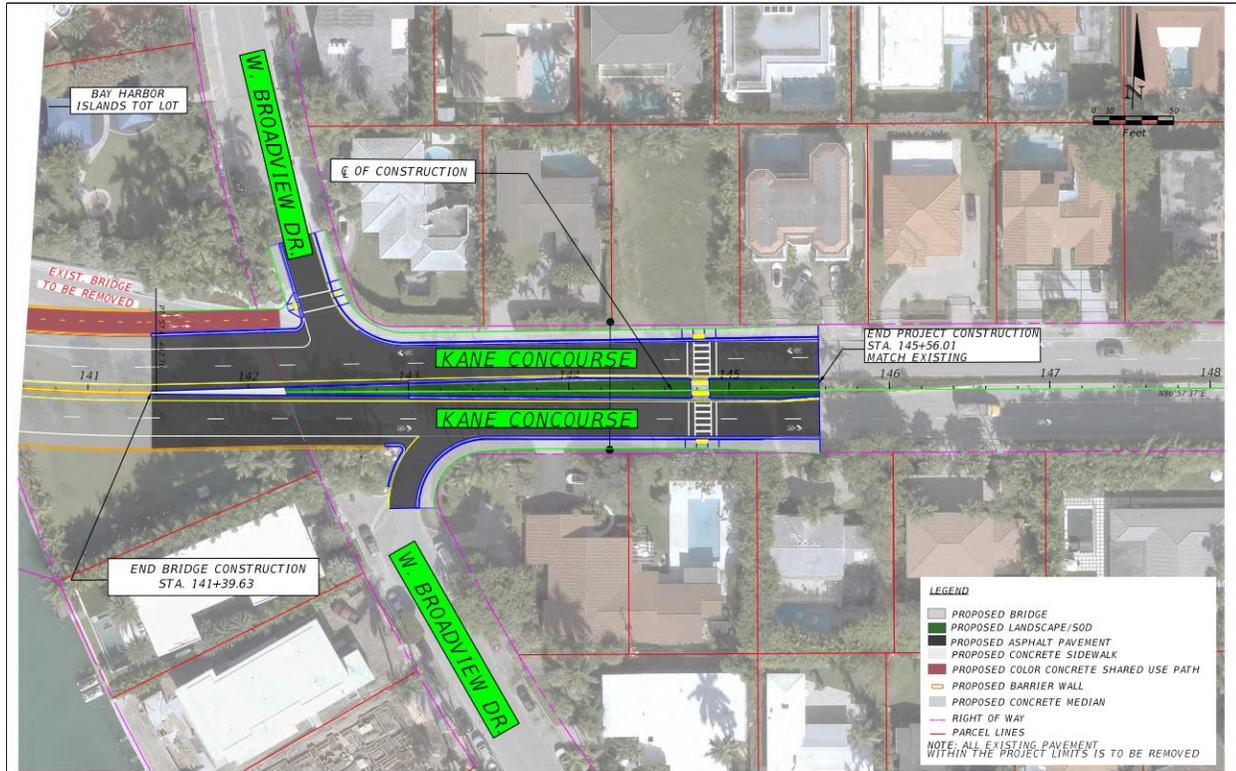

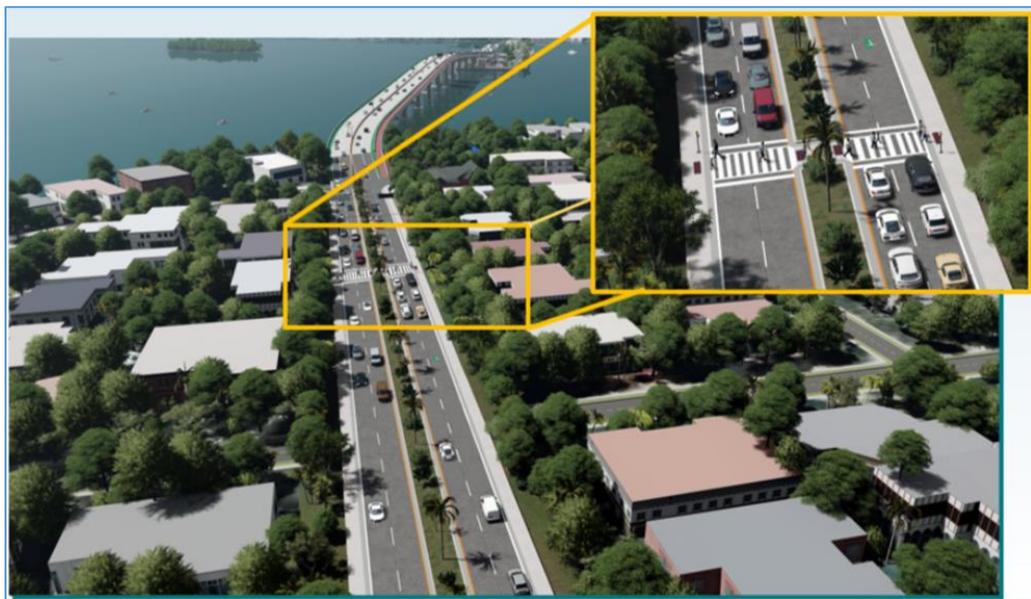

Figure 5-4 Pedestrian Mid-Block Crossing east of W. Broadview Drive

## 5.2 Future Segment Volumes

**Table 5-1** provides the estimated 2030 opening and 2050 design volumes for the weekday and weekend AADT. These forecasted volumes are based on the selected 1% annual linear growth rate.

**Table 5-1 Estimated Future Daily Traffic Counts**

Count Station	Count Location	Scenario	Weekday AADT	Weekend AADT
1	Broad Cswy, West of Chevron Gas Station	2030 Opening	26,900	18,800
		2050 Design	31,900	22,300

## 5.3 Future Intersection Volumes

Intersection volumes for opening year and design year No-Build and Build scenarios are illustrated in **Figure 5-5** through **Figure 5-8**. Opening and Design year figures include the freeway merge locations and the stopped-controlled intersection locations. As stated at the beginning of Section 5.0 the stopped-controlled intersections in the Build model are developed from vehicles entering and exiting Chevron, both on the frontage road.

Figure 5-5 2030 No-Build Turning Movement Volumes

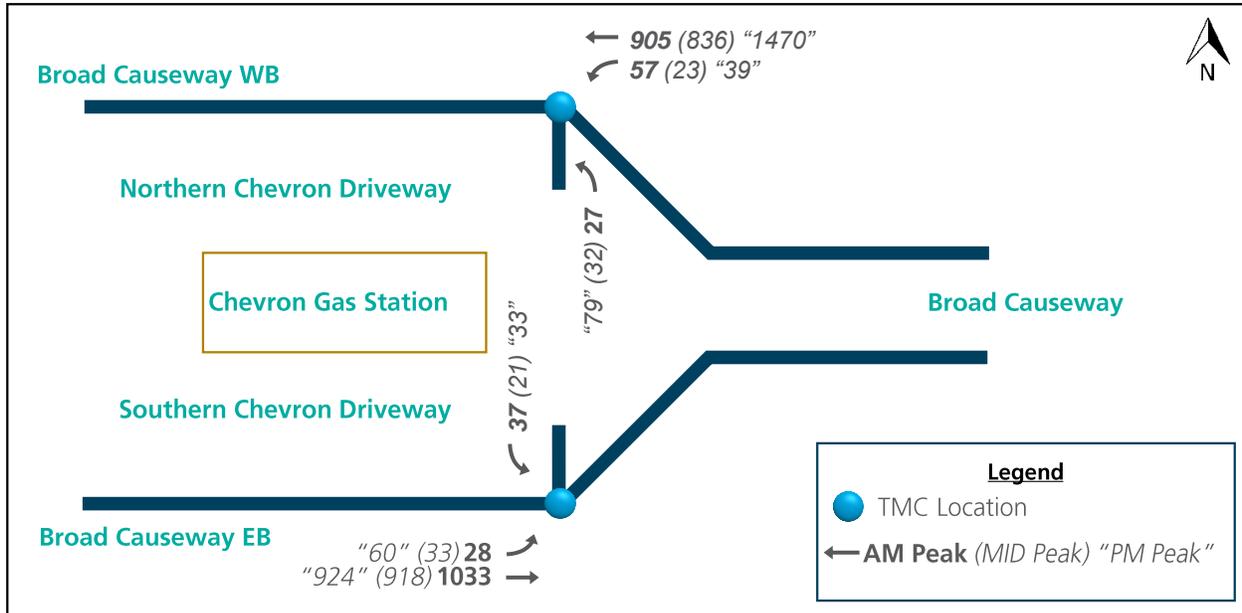

Figure 5-6 2050 No-Build Turning Movement Volumes

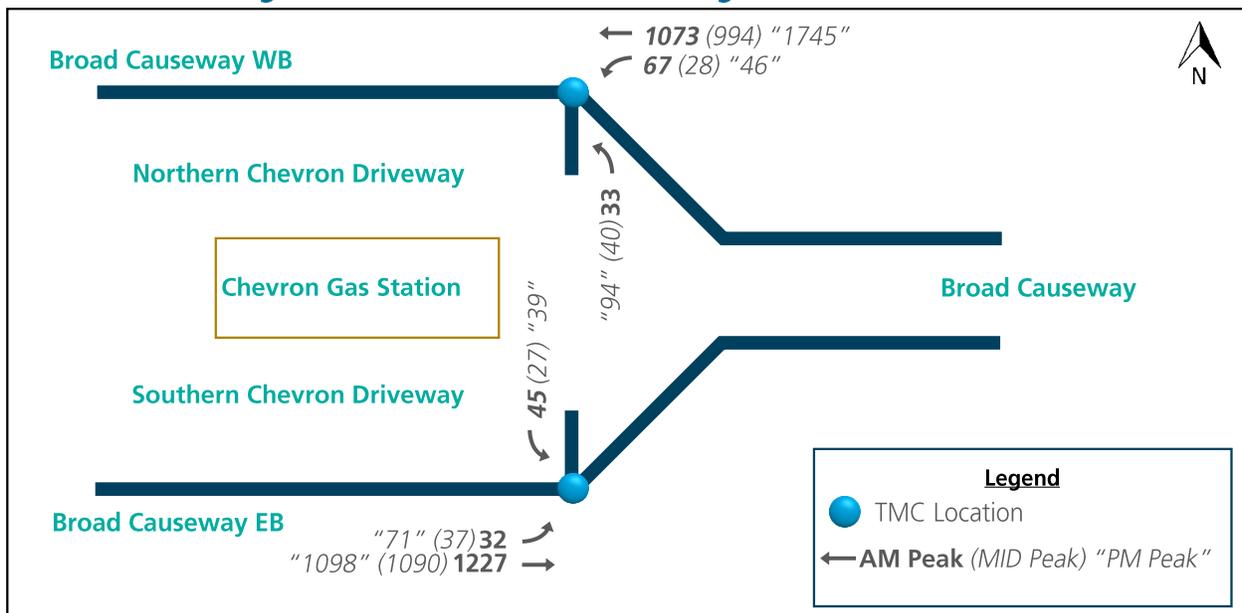

Figure 5-7 2030 Build Turning Movement Volumes

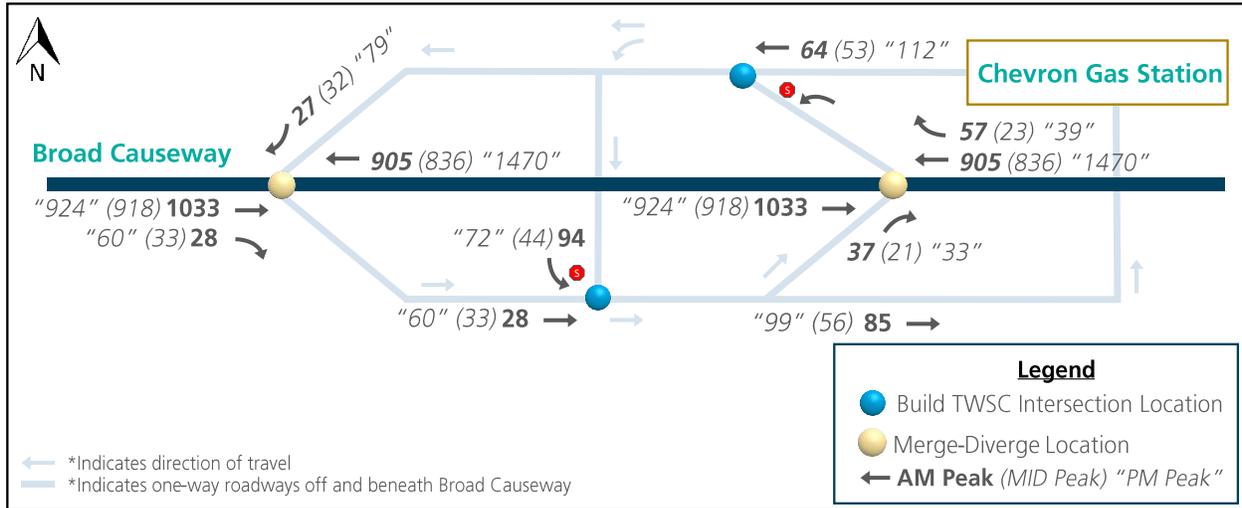

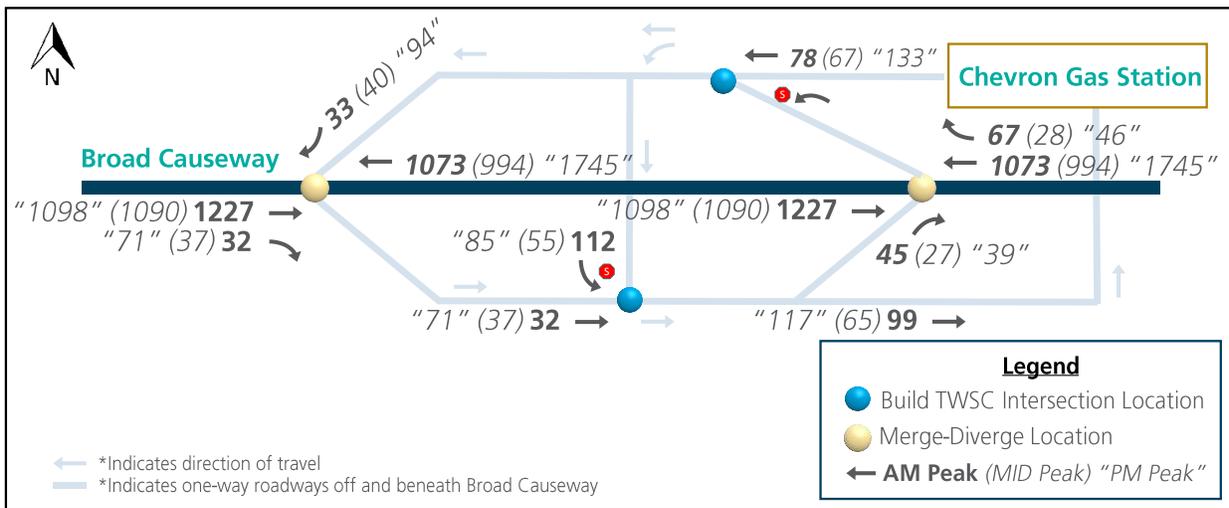

Figure 5-8 2050 Build Turning Movement Volumes

## 5.4 Future Segment Analysis

For future year segment analysis for both the no-build and build scenarios are analyzed using peak hour and daily segment volumes. The segment volumes were obtained by growing existing counts by an 1.0% annual growth factor. **Table 5-2** summarizes level of service and volume to capacity for daily volumes using 2023 FDOT Generalized Service Volume Tables. **Table 5-3** summarizes level of service and travel speed using the SimTraffic Arterial Level of Service Reports

The future segment analysis, which is based on volume comparison to the 2023 FDOT Generalized Service Volume Tables, results in a daily V/C ratio below 0.87.

The future peak hour future segment analysis was based on future travel speed collected from SimTraffic, each peak period and approach exceed 80% of the base free-flow speed. The LOS criteria from HCM urban street facilities results in a LOS of A for all conditions. All future conditions are within the target of LOS D.

**Table 5-2 Future Segment Volume Analysis Summary (Daily)**

Roadway	Extents	Scenario	Volume	Service Volume Capacity	v/c	LOS	Targeted LOS
Broad Causeway	Bayshore Dr to West Broadview Dr	2030 Build	26,900	36,100	0.74	D	D
		2050 Build	31,900	36,100	0.88	D	D

			MID	28	28	A	A	D
			PM	28	26	A	A	D
		2050 Build	AM	28	27	A	A	D
			MID	28	28	A	A	D
			PM	28	26	A	A	D

## 5.5 Future Intersection Analysis

Intersection capacity analysis for the future year no-build scenario utilized the Highway Capacity Manual (HCM6) methodology and was completed using Synchro software. The no-build analysis for the stop-controlled access to and from the Chevron gas station is presented in **Table 5-4** and **Table 5-5**. All movements result in a LOS of C or better except for the 2050 No-Build PM stop at the northern driveway access along the westbound direction, which resulted in an LOS D.

For the Build scenarios merging points, Freeway Merge and Diverge Level of Service (LOS) was completed using HCS7 software. Build year demand volumes for the intersection and merge location on each approach was illustrated in **Figure 5-5** through **Figure 5-8**.

Based on the results, each build scenario intersection results in a LOS of A or better and each merge and diverge report results in a LOS of C or better. The results from the future Build analysis are presented in **Table 5-6** through **Table 5-9**. Given the design year analysis for each peak period was within acceptable LOS ranges year 2030 merge and diverge analysis was removed for brevity.

The unique features of Broad Causeway generated a final speed adjustment in the analysis. In HCM the freeway merge and diverge procedure, the minimum free-flow speed is 45 mph. The posted speed limit along Broad Causeway is 30 mph. To replicate field conditions, a 0.9 final speed factor was applied to the freeway free-flow speed.

## 5.6 Future Multimodal Analysis

Determining LTS for a facility is based on a variety of factors and conditions, such as the presence and configuration of dedicated or mixed traffic facilities. Roadways were assigned a stress level of one to four, with LTS 1 signifying very low stress and LTS 4 signifying high stress. The design plans for the bridge reconstruction increased the bridge shoulder that bicycles are permitted to use and develops a shared use path vertically separated from the roadway.

In the existing conditions the level of traffic stress for a pedestrian and bicyclist crossing the bridge was LTS 4 (which is defined as a route that is impassable by a wheeled mobility device or a level tolerated only by those with limited route choice and/or a cycling enthusiast). After reviewing each characteristic in future build conditions, the level of traffic stress for pedestrians and bicyclist is expected to be LTS 1, which is a level that can be tolerated by all users. The installation of a shared use path separated from Broad Causeway is expected to provide a safe and comfortable facility for all users willing to use the shared path, which improved the LTS score. Additionally, if bicyclists would prefer to use the roadway, they are permitted to ride within the newly installed 8-foot shoulder. The width of the shoulder concludes cyclist utilizing the shoulder along the roadway is expected to be Level of Traffic Stress 3 (which is a level tolerated by confident cyclists who still prefer having their own dedicated space for riding).

Illustration of the Level of Stress flow chart is provided in **Appendix 7.5**.

## 5.7 Predictive Crash Analysis

The future year design alternative safety analysis is performed using the predicted average crash frequency process outlined in the Highway Safety Manual (HSM) 1<sup>st</sup> Edition. This HSM provides a predictive method for estimating expected average crash frequencies at individual sites and corridors. This method relies on safety performance functions (SPF) that estimate predicted average crash frequency as a function of traffic volume and roadway characteristics (e.g., number of lanes, median type, shoulder width, etc). The goals of this process are to evaluate the safety effects of roadway improvements and to compare relative safety performance of design alternatives.

Although there are design recommendations throughout the project study area, the segment with the most significant changes to the typical section is the bridge segment of the Broad Causeway from east of the Chevron Gas Station to the eastern edge of the bridge; or essentially the undivided portion of the corridor. This coincides with Segment 2 identified in **Figure 3-10**. Therefore, the predictive method is only performed for this segment. For HSM analysis purposes this corridor was assumed to be an urban arterial (HSM Chapter 12).

The existing conditions of the study area were inventoried by visual observation and verified by survey in the field. The proposed design elements are included as part of the design alternative and illustrated in the preliminary engineering reports associated with this project. **Table 5-10** provides a list of design elements comparing the design of the existing bridge typical section versus the proposed redesign typical section. These elements are used in the HSM analysis.

**Table 5-10 Geometric Elements Impacting HSM (Bridge Segment Only)**

<i>Design Element</i>	<i>Existing</i>	<i>Proposed Design</i>
<i>Lane Width</i>	<i>10-feet</i>	<i>11-feet</i>
<i>Median Treatment</i>	<i>Undivided</i>	<i>Barrier</i>
<i>Inside Shoulder</i>	<i>None</i>	<i>4-feet</i>
<i>Outside Shoulder Width</i>	<i>2.5-feet</i>	<i>8-feet</i>
<i>Bicycle Lanes</i>	<i>Shared with Traffic</i>	<i>May ride on bridge shoulder or on 14-foot physically separated shared used path</i>

The safety performance functions (SPF) were used for estimating predicted average crash frequency as a function of traffic volume. Existing and design year volumes developed in Section 4 of this report are used for analysis. The predicted crash frequencies summary results are provided in **Table 5-11** . It's noted that the intent of the predictive analysis is to show impacts of the design decisions for the wider shoulders and separated medians. Therefore, FDOT HSM calibration factors were not used in this analysis given this bridge segment is not similar to the typical state roads where these calibration factors were developed from. The results show that with the design changes proposed in this study the previously undivided segment of the Broad Causeway is predicted to go from 3.4 crashes per year to 2.3 crashes per year by the design year 2050. It's noted that for the Design Year Build the median width was set to the lowest option of 10 feet; actual median width total is 10 feet but 4 feet on either side of the barrier wall.

HSM worksheet output summary files are provided in **Appendix 7.6**.

**Table 5-11 HSM Predictive Crash Analysis Results**

<i>Crash Severity Level</i>	<i>Design Year No Build (Predicted crashes/year)</i>	<i>Design Year Build (Predicted crashes/year)</i>
<i>Property Damage Only</i>	<i>2.4</i>	<i>1.6</i>
<i>Fatal and Injury</i>	<i>1.0</i>	<i>0.7</i>
<i>Total Crashes</i>	<i>3.4</i>	<i>2.3</i>

### HSM Commentary

Although the HSM predictive analysis shows a decrease in crashes these results should be further examined with the actual project improvements in mind. The current version of the HSM does not account for introduction of a separated bicycle facility or the elimination of the draw bridge interruptions to traffic.

The following examples further examine the logical benefits to safety that are not well reflected in the HSM process. The crash values used include 5-years of crash history for the undivided segment of the study area.

- Separated Bicycle Facility: In the existing condition there were 4 bicycle crashes (all resulting in injury) and in the proposed condition there is a physically separated shared use path crossing the bridge, thus eliminating vehicle and bicycle interactions.
- Separated Median: In the existing condition there were 2 head-on crashes (both resulting in an injury), and in the proposed condition there is expected to be zero head on crashes with the physical separation between opposing travel lanes. As for other crash types, installing a median barrier has a documented Crash Modification Factor of 0.14 (or 86% reduction for all crash types and severities. Source: cmfclearinghouse.org CMF ID# 974)
- Removal of Bridge Stop Control: In the existing condition there was 9 rear-end crashes, which were partially resulting from there being a stop control on the bridge. However, in a possible proposed condition includes fixed bridge, meaning the interruptions will be removed, and is reasonable to expect the rear-end crashes to also decrease.

This additional summary is provided to show that the unique elements of the proposed conditions are not well reflected in the current HSM, thus indicating that results of the HSM methodology are also not appropriately representative of all the safety benefits expected from the proposed improvements.

## 5.8 Future Evacuation Plans

The Broad Causeway serves as part of the emergency evacuation route network designated by the Florida Division of Emergency Management (FDEM) and Miami-Dade County. Use of the Causeway plays a critical role in facilitating traffic between the beaches and the mainland of Miami during emergency evacuation periods.

While evacuation planning is not typical of average day or typical peak hour analysis it's important to this facility due to its proximity and limited access options to and from the coastal neighborhoods.

One evacuation strategy to increase the eastbound capacity of the Causeway is to consider contra-flow operations, or partial contra-flow operations. The Town of Bay Harbor Islands shared that any procedure to allow 3-lane/1-lane configuration during evacuation would be handled by the Police Department. Discussion with team decided that the Police Department could develop a protocol considering a rigid median traffic barrier and the protocol would extend beyond project limits (stoplight to stoplight) to ensure safety. Because this operation would be executed only in times of extreme needs its impacts are not analyzed in this project.

## 6.0 Summary of Analysis Results

Based on the traffic performance analysis, it is determined that build reconfigurations of the Broadway Causeway Bridge and adjacent improvements to the Chevron Gas Station results in a beneficial impact. The improvements to the bridge cross section, such as increased bicycle width and separated multimodal shared use path results in improving the Level of Traffic Stress to 1, a level that can be tolerated by all users.

Improvements at the gas station access results in a LOS C or better. The reconfigurations occur from new locations where traffic merge and diverge as well as a stopped controlled intersection between entering and exiting vehicles. The design merge and diverge areas resulted in LOS of B and design stopped controlled intersection resulted in LOS A.

Based on the multimodal analysis, it is determined that the build reconfigurations improve traffic operations as well as the level of traffic stress for pedestrians and bicyclist. The shared use path separated from Broad Causeway improves the safety and comfortability for multimodal movement.

# 1. Introduction

The purpose of this Traffic Analysis Methodology Report (TAMR) is to outline the project limits, assumptions, and analysis methodologies that will be employed in the development of the Project Traffic Analysis Report (PTAR) along (SR-922) Broad Causeway in Miami-Dade County, Florida. The analysis will document existing and future conditions and follow the process outlined in FDOT's *Project Development and Environmental (PD&E) Manual*. The results of the PTAR will be prepared and documented as part of the Broad Causeway Bridge Replacement PD&E study. All raw data and supporting information referenced in the analysis will be included with the PTAR deliverable.

## 1.1. Project Description & Objective

This project involves an approximate 0.78 mile in length segment of SR-922 (Broad Causeway) from Broad Causeway Island on the west side and to the east at the intersection with West Broadview Drive. The SR-922 (Broad Causeway) study segment roadway classified as an urban minor arterial and connects the Town of Bay Harbor Islands and Bal Harbor/Surfside with the City of North Miami, within Miami-Dade County.

The existing bridge consists of four 10-foot wide travel lanes (two in each direction) without a raised median. The outside travel lanes also include shared-use markings to accommodate bicycles. In addition, a raised sidewalk is present on each side of the bridge, with a width that varies from 22 to 36 inches. The sidewalks run adjacent to the travel lanes and are not buffered with green space or guardrails.

The proposed project is intended to improve the mobility, operations, and safety of SR-922 and reduce the travel impacts of the Chevron gas station and existing drawbridge. Additional consideration of bicycle lanes and sidewalks will be evaluated along SR-922. SR-922 also serves as a primary hurricane evacuation route.

## 1.2. Study Area

The 0.78 mile study segment of SR-922 (Broad Causeway) is an urban minor arterial that begins at the intersection of SR-922 and Bayshore Drive and extends east to the intersection of SR-922 and West Broadview Drive.

The existing intersections listed below will be analyzed as part of this study.

- SR-922 (Broad Causeway) and Northern Chevron Driveway
- SR-922 (Broad Causeway) and Southern Chevron Driveway

A map of the study area is presented in **Figure 1-1**.

Figure 1-1 - Study Area Map and TMC Location

## 2. Traffic Analysis Assumptions

A traffic operations analysis of the corridor and previously identified intersections will be performed based on methodologies included in the FDOT *Traffic Analysis Handbook (2021)* and the FDOT *2023 Multimodal Quality/Level of Service Handbook*. The analysis will include the performance metrics for the existing conditions, no build alternative, and build alternatives as described in the following sections.

### 2.1. Analysis Years

The following years represent the existing year, opening year, and design year for corridor and intersection performance evaluation. Analysis years for regional demand model runs are explained further in the Project Traffic Forecasting section of this report.

- Existing Year = 2023
- Opening Year = 2030
- Design Year = 2050

## 2.2. Analysis Periods

Daily, AM peak, MID peak, PM, and Weekend peak traffic periods will be evaluated consistent with the analysis years. Intersection and corridors traffic data collections will be adjusted based on the appropriate seasonal factors.

## 2.3. Project Alternatives

The Opening Year, and Design Year operational analyses for this study will include an evaluation of a No-Build scenario and a Build scenario. The No-Build scenario will reflect the 10-foot wide, four-lane existing roadway facility from Bayshore Drive to West Broadview Drive. TSM&O strategies will be taken into consideration throughout the study as well.

## 2.4. Performance Measures

Performance measures will be based on the FDOT policy of target level of service (LOS) for State Highway System arterials in urban areas. The target LOS for intersections and corridors will be LOS D.

### Segments

For segment performance measures the following list will be developed using AADT and DHV.

- Travel Time
- Average Speed
- Arterial Level of Service
  - Daily will use FDOT's Generalized Tables based on Context Classification
  - AM, MID, PM, and Weekend Peak will use HCM procedures
- Volume to Capacity Ratios
- Multimodal LOS

### Intersections

For intersection performance measures the following list will be developed based on the intersection movement, approach, and overall intersection during the AM, MID, and PM peak hours.

- Control Delay
- Level of Service
- Volume to Capacity Ratios
- 95<sup>th</sup> percentile Queue Length

## 2.5. Traffic Analysis Tools

Segment and intersection traffic analysis will be completed using HCS7 and Synchro with SimTraffic analysis programs. Both of these programs utilize operational performance methodologies of the *Highway Capacity Manual*, 6<sup>th</sup> Edition (HCM6), and have the ability to generate the performance measures listed above. Where applicable, HCM reports will be provided for all intersections and corridors. Where HCM6 methodologies are not applicable due to intersection geometry or phasing, previous versions of HCM will be used and will be documented in the analysis and reporting.

## 3. Data Collection

Data collection will consist of existing geometric conditions, existing and historical traffic data, and historical crash data. The following sections describe each in more detail.

### 3.1. Existing Conditions

Data related to the existing site conditions and geometry will be detailed in the full PTAR. These data and analysis processes will include the following:

#### Existing Geometric Review

- Aerial photo and/or field drawing of roadway geometry: An existing conditions plan will be provided.
- Existing geometry and movements of each study intersection (including number/types of lanes): A site location map depicting the study area will be provided. Existing lane striping facilitating present traffic movements will be marked.
- Lengths of right & left turn lanes/tapers: Tables will be provided for all links in the analysis detailing actual lengths of auxiliary lanes, and median opening locations.

### 3.2. Traffic Data

Traffic data will be collected in the field, and may be supplemented by data obtained from FDOT, the Miami-Dade County Open Data Hub, and relevant recent transportation studies. Existing site traffic data to be collected will include:

#### Turning Movement Counts

Seven-hour Turning Movement Counts (TMCs) will be conducted at two (2) intersections:

- SR-922 (Broad Causeway) and Northern Chevron Driveway
- SR-922 (Broad Causeway) and Southern Chevron Driveway

The TMCs will be conducted during a typical weekday from 7:30-9:30 am, 12:00-2:00 pm, and 3:00-6:00 pm based on the review of recent FDOT count station reports in the study vicinity.

Multi-modal data including pedestrians, bicycles, and heavy vehicles will be classified separately. All counts will be summarized in 15-minute intervals with hourly totals and AM, MID, and PM peak hour summaries for the overall intersection.

#### Directional Approach Counts

24-hour directional approach counts will be conducted on each approach of the two study intersections. The approach counts will be conducted during a week period and will coincide with the TMC collection. Counts will be balanced between adjacent intersections where minimal traffic breaks exist between the intersections. All counts will be summarized in 15-minute intervals with hourly and daily totals for each direction and the combined total. Additionally, the Town will provide directional counts that are collected by the all-electronic toll collection system. These counts will be used to validate 24-hour directional approach counts.

#### Vehicle Classification Counts

24-hour Vehicle Classification Counts will be conducted at two locations on the SR-922 mainline (west of the Chevron driveway). The classification counts will be conducted during a week period. ATRs with road tubes will be used. Vehicles will be classified into the 13 FHWA categories, with daily percentages calculated for each category. All counts will be summarized in 15-minute intervals with hourly and daily totals for each direction and the combined total.

### 3.3. Safety Data and Analysis

Detailed crash data will be obtained from Signal Four Analytics, which as of April 2023 is the exclusive FDOT statewide crash database. Crash information for the most recent five years (2018-2022) will be obtained for the Broad Causeway mainline and side street intersection influence/driveway areas. The data will include but not be limited to: the number and location of crashes, crash types, and severity (fatalities, injuries, property damage), and contributing causes

## 4. Project Traffic Forecasting

### Travel Demand Model

Travel Demand Forecasting analysis will be incorporated into the PTAR to develop future-year design traffic volumes. The Southeast Florida Regional Planning Model (SEFRPM) Version 8.524 will be utilized in the development of future travel demand. The SEFRPM has a base year of 2015 and a horizon year of 2045 and projects traffic by assumed growth rates and adding constructed and committed roadway improvements. Actual 2015 AADT volumes and 2015 base year model volumes on SR-922 will be compared to evaluate the ability of the model to replicate actual traffic volumes. A 2030 and 2050 model network will be interpolated by using the 2015 base year network and the 2045 forecast.

### Proposed Growth Rate

Historical traffic counts, 2023 data collection efforts, travel demand model forecasting, and forecasted population projections will all be referenced to provide a reasonableness check to the model's future year traffic projections. Based on all available data a proposed growth rate will be presented for future volume development use.

### 4.1. Development of Directional Design Hour Volumes

Directional design hour volumes (DDHVs) will be developed for the two intersection limits of SR-922 using the TURNS5 program, which applies K and D factors to the projected AADTs. Observed turn percentages are then applied and the program calculates balanced intersection volumes. The TURNS5 output will be reviewed for reasonableness and volumes will be smoothed where necessary. AM, MID, and PM peak hour DDHVs will be developed for 2030, 2040, and 2050, for No-Build and Build alternatives.

Standard peak hour (K) factors (9.0% for urban areas) will be used for the peak hour conditions. Directional (D) factors will be obtained from Florida Traffic Online. D factors will also be calculated from the 24-hour approach count and eight-hour TMC data. If calculated D factors vary significantly from FDOT D factors, adjustments to the factors will be recommended. Truck factors will be developed based on classification counts performed along Pensacola Street.

# 5. Traffic and Safety Analysis

## Existing Operational Analysis

The existing analysis will be performed using existing signal timings at signalized intersections. Each of the peak-hour traffic scenarios collected during the data collection task will be applied to the model and operational performance measures.

## Future Operational Analysis (No-Build and Build Alternatives)

For future segment analysis, the forecasted volume AADT and DHV will be used to analyze corridor-level performance measures as described earlier. For intersections, the future model analysis will use the demand model generated and refined turning movement counts for each scenario to generate Synchro intersections models of the anticipated traffic conditions. Future analysis will be performed with reasonably expected signal timing parameters based on geometry changes and volume growth. The performance measures noted above will also be utilized for future conditions.

The potential network modifications will each be tested in proposed conditions models and revised performance measures reported to assess the potential effectiveness of different improvement scenarios. All scenarios tested will be summarized in a report of the analysis methodologies, assumptions, and outputs.

## Safety Analysis

For safety analysis individual crash records will be reviewed to identify patterns of recurring crashes, to determine underlying causes, and to identify countermeasures to improve safety.

Where typical sections or geometric changes are proposed anticipated changes in crash patterns will be analyzed and documented in the PTAR. Where applicable, safety analysis will be performed using the *Highway Safety Manual* (HSM) predictive crash analysis methods utilizing the Safety Performance Functions. For proposed improvements that are not included in the HSM, applicable Crash Modification Factors (CMF), either published by FDOT or the national CMF Clearinghouse will be utilized.

# Projections of Florida Population by County, 2025–2050, with Estimates for 2022

Stefan Rayer, Population Program Director

The Bureau of Economic and Business Research (BEBR) has been making population projections for Florida and its counties since the 1970s. This report presents our most recent set of projections and describes the methodology used to construct those projections. To account for uncertainty regarding future population growth, we publish three series of projections. We believe the medium series is the most likely to provide accurate forecasts in most circumstances, but the low and high series provide an indication of the uncertainty surrounding the medium series. It should be noted that these projections refer solely to permanent residents of Florida; they do not include tourists or seasonal residents.

## State Projections

The starting point for the state-level projections was the decennial census count for April 1, 2020. Because the detailed census counts by age and sex are not yet available, we used the BEBR age and sex estimates for April 1, 2020, which were controlled to the Census 2020 count of total population. Projections were made in one-year intervals using a cohort-component methodology in which births, deaths, and migration are projected separately for each age-sex cohort in Florida.

Survival rates were applied by single year of age and sex to project future deaths in the population. These rates were based on Florida Life Tables for 2012–2018, using mortality data published by the Office of Vital Statistics in the Florida Department of Health. We adjusted the survival rates for 2020–2027 to make them

consistent with recent mortality trends, and to align the projected deaths with those from the State of Florida’s Demographic Estimating Conference (DEC) held February 10, 2023. After 2027, we made small adjustments to the survival rates based on projected changes in survival rates released by the U.S. Census Bureau.

Domestic migration rates by age and sex were based on Public Use Microdata Sample (PUMS) files from the 2011–2019 American Community Survey (ACS) 1-year estimates and 2015–2019 ACS 5-year estimates. We calculated an average of those two sets of migration estimates; projections based on input data from more than one time period tend to be more accurate than those based on a single time period. By combining 1-year ACS estimates, which are more current, with 5-year ACS estimates, which are more stable, we make use of the different strengths of each type of ACS data.

We applied smoothing techniques to the age/sex-specific migration rates to adjust for data irregularities caused by small sample size. The smoothed in- and out-migration rates were weighted to account for recent changes in Florida’s population growth rates. Projections of domestic in-migration were made by applying weighted in-migration rates to the projected population of the United States (minus Florida), using the most recent set of national projections produced by the U.S. Census Bureau. Projections of out-migration were made by applying weighted out-migration rates to the Florida population. In both instances, rates were calculated separately for males and females for each age up to 90 and over.

The distribution of foreign immigrants by age and sex was also based on averages of the patterns observed over the same time periods using the same ACS data sets as for domestic migration. Again, we smoothed the estimates to account for irregularities in the age/sex distribution of immigrants.

Projections were made in one-year intervals, with each projection serving as the base for the following projection. Projected in-migration for each one-year interval was added to the survived Florida population at the end of the interval and projected out-migration was subtracted, giving a projection of the population age one and older.

Births were projected by applying age-specific birth rates (adjusted for child mortality) to the projected female population. These birth rates were based on Florida birth data for 2012–2018 published by the Office of Vital Statistics in the Florida Department of Health. They imply a total fertility rate (TFR) of 1.75 births per woman. These rates were reduced in the short-term projections to make them consistent with recent fertility trends, and to align the projected births with those from the February 10, 2023 DEC. The long-term projections imply about 1.80 births per woman.

The medium projections of total population for 2023–2027 were adjusted to be consistent with the state population forecasts for those years produced by the February 10, 2023 DEC. None of the projections after 2027 had any further controls.

In the addition to the medium projections, we also created low and high projections for Florida. The low and high projections for the state should not be considered as low and high growth scenarios; rather, they represent an indication of the uncertainty surrounding the medium projections. The range was based on average projection errors of previous BEBR state-level projections.

In this publication, we provide projections for 2025, 2030, 2035, 2040, 2045, and 2050. State projections for other years are available by request.

## County Projections

The cohort-component method is a good way to make population projections at the state level but is not necessarily the best way to make projections at the county level. Many counties in Florida are so small that the number of persons in each age-sex category is inadequate for making reliable cohort-component projections, given the lack of detailed small-area data. Even more important, county growth patterns are so volatile that a single technique based on data from a single time period may provide misleading results. We believe more useful projections of total population can be made by using several different techniques and historical base periods.

For counties, we started with the population estimate constructed by BEBR for April 1, 2022. We made projections for each county using five different techniques in five-year increments. The five techniques were:

1. Linear – the population will change by the same number of persons in each future year as the average annual change during the base period.
2. Exponential – the population will change at the same percentage rate in each future year as the average annual rate during the base period.
3. Share-of-growth – each county’s share of state population growth in the future will be the same as its share during the base period.
4. Shift-share – each county’s share of the state population will change by the same annual amount in the future as the average annual change during the base period.
5. Constant-share – each county’s share of the state population will remain constant at its 2022 level.

For the linear and share-of-growth techniques we used base periods of two, ten, and twenty years (2020–2022, 2012–2022, and 2002–2022), yielding three sets of projections for each technique. For the exponential and shift-share techniques we used base periods of five and fifteen years (2017–2022 and 2007–2022), yielding two sets of projections for each technique. The constant-

share method was based on data for a single year (2022).

This methodology produced eleven projections for each county for each projection year (2025, 2030, 2035, 2040, 2045, and 2050). From these, we calculated five averages: one using all eleven projections (AVE-11), one that excluded the highest and lowest projections (AVE-9), one that excluded the two highest and two lowest projections (AVE-7), one that excluded the three highest and three lowest projections (AVE-5), and one that excluded the four highest and four lowest projections (AVE-3). Based on the results of previous research, we designated the average that excluded the three highest and three lowest projections (AVE-5) as the default technique for each county. We evaluated the resulting projections by comparing them with historical population trends and with the level of population growth projected for the state as a whole. For counties in which AVE-5 did not provide reasonable projections, we selected the technique producing projections that fit most closely with our evaluation criteria.

For 61 counties we selected AVE-5, the average in which the three highest and three lowest projections were excluded. In the remaining six counties, we selected projections made from an individual technique or calculated a custom average (e.g., an average of two individual techniques). These include Baker, Calhoun, Gadsden, Hardee, Jackson, and Monroe counties.

We also made adjustments in several counties to account for changes in institutional populations such as university students and prison inmates. Adjustments were made only in counties in which institutional populations account for a large proportion of total population or where changes in the institutional population have been substantially different than changes in the rest of the population. In the present set of projections, adjustments were made for Alachua, Baker, Bradford, Calhoun, Columbia, DeSoto, Dixie, Franklin, Gadsden, Gilchrist, Glades, Gulf, Hamilton, Hardee, Hendry, Holmes, Jackson, Jefferson, Lafayette, Leon, Liberty, Madison, Okeechobee, Santa Rosa, Sumter, Suwannee, Taylor, Union, Wakulla, Walton, and Washington counties.

## Range of County Projections

The techniques described in the previous section were used to construct the medium series of county projections. This is the series we believe will generally provide the most accurate forecasts of future population change. We also constructed low and high projections to provide an indication of the uncertainty surrounding the medium county projections. The low and high projections were based on analyses of past population forecast errors for counties in Florida, broken down by population size and growth rate. They indicate the range into which approximately three-quarters of future county populations will fall, if the future distribution of forecast errors is similar to the past distribution.

The range between the low and high projections varies according to a county's population size in 2022 (less than 30,000; 30,000–199,999; and 200,000 or more), rate of population growth between 2012 and 2022 (less than 7.5%; 7.5–15%; 15–30%; and 30% or more), and the length of the projection horizon. Our studies have found that the distribution of absolute percent errors tends to remain fairly stable over time, leading us to believe that the low and high projections provide a reasonable range of errors for most counties. It must be emphasized, however, that the actual future population of any given county could be below the low projection or above the high projection.

For the medium series of projections, the sum of the county projections equals the state projection for each year (except for slight differences due to rounding). For the low and high series, however, the sum of the county projections does not equal the state projection. The sum of the low projections for counties is lower than the state's low projection and the sum of the high projections for counties is higher than the state's high projection. This occurs because potential variation around the medium projection is greater for counties than for the state as a whole.

**Technical Memorandum**

**Projections of Florida Population by County, 2020-2070**

**Prepared for**

**Forecasting and Trends Office**

**Florida Department of Transportation**

**October 2020**

---

## Introduction

Long-term population projections are needed to support the statewide transportation planning studies such as the Florida Transportation Plan (FTP) and the Multi-use Corridors of Regional Economic Significance (M-CORES) program. This Technical Memorandum describes the methodology used to develop Florida's population projections for the next 50 years from 2020 to 2070 in five-year increments for all 67 counties and presents the results based on the methodology.

The Bureau of Economic and Business Research (BEBR) at the University of Florida has been making population projections for Florida and its counties since the 1970s. The latest report was published in January 2020 and it contains the most recent set of projections from 2020 to 2045. To account for uncertainty regarding future population growth, BEBR publishes three series of projections: low, medium, and high. The medium series is typically considered more accurate, while the low and high series indicate the uncertainty surrounding the medium series. It should be noted that these projections include only permanent residents. Tourists or seasonal residents are not included.

The methodology used by BEBR to develop 2020-2045 population projections has been used for many years and has proven to be both practical and reliable. The medium series of BEBR projections were adopted for years up to 2045. For years from 2050 to 2070, population projections were developed using the BEBR methodology. However, to ensure that the BEBR methodology was properly applied, a two-step process was followed. The first step was to replicate the BEBR 2020-2045 population projections with the same methodology and data sources. The second step was to extend the population projections an additional 20 years from 2050 to 2070 with necessary adjustments and reasonableness checks. The following sections describe in more detail the two-step process.

---

## Step 1 – BEBR Methodology and Replicating 2020-2045 Population Projections

### State Projections

The starting point for the state-level projections was the April 1, 2010 census population count by age, sex, race, and Hispanic origin, as adjusted by the National Center for Health Statistics (NCHS) in the Vintage 2017 bridged race population estimates. Projections were made in one-year intervals using a cohort-component methodology in which births, deaths, and migration are projected separately for each age-sex cohort in Florida for non-Hispanic whites, non-Hispanic nonwhites, and Hispanics.

Three different sets of assumptions are made to provide low, medium, and high series of projections. Although the low and high series do not provide absolute bounds on future population change, they provide a reasonable range in which Florida's future population is likely to fall. The medium projections of total population for 2020-2024 were adjusted to be consistent with the state population forecasts for those years produced by the State of Florida's Demographic Estimating Conference (DEC) held on December 3, 2019. None of the projections after 2024 had any further adjustments.

BEBR indicates that medium series is the most likely to provide accurate forecasts in most circumstances. Therefore, the medium projections of state total population for 2020-2045 were directly used when replicating projections of county population for 2020-2045.

### County Projections

The cohort-component method is appropriate to make population projections at the state level but is not sufficient to make projections at the county level. Many counties in Florida have a population so small that the number of persons in each age-sex category is inadequate for making reliable cohort-component projections, given the lack of detailed small-area data. In addition, county growth patterns are often volatile that a single technique based on data from a single time period may produce misleading results. As a result, BEBR recommends using several different techniques and historical base periods to project total populations at the county level.

BEBR started with the population estimates constructed for April 1, 2019, and made projections for each county using the following five (5) different techniques:

- **Linear** – the population will change by the same number of persons in each future year as the average annual change during the base period.
- **Exponential** – the population will change at the same percentage rate in each future year as the average annual rate during the base period.
- **Share-of-growth** – each county's share of state population growth in the future will be the same as its share during the base period.
- **Shift-share** – each county's share of the state population will change by the same annual amount in the future as the average annual change during the base period.
- **Constant-share** – each county's share of the state population will remain constant at its 2019 level.

For the linear and share-of-growth techniques, BEBR used base periods of two, ten, and twenty years (2017–2019, 2009–2019, and 1999–2019), yielding three sets of projections for each

technique. For the exponential and shift-share techniques, BEBR used base periods of five and fifteen years (2014–2019 and 2004–2019), yielding two sets of projections for each technique. The constant-share method was based on data for a single year (2019). **Table 1** shows a summary of the techniques used, the corresponding base period(s), and the number of population projections created for each county for each projection year.

**Table 1 Population Projection Techniques and Base Periods**

Technique	Base Period	Number of Projections
<b>Linear</b>	2017–2019 (two-year period) 2009–2019 (ten-year period) 1999–2019 (twenty-year period)	3
<b>Exponential</b>	2014–2019 (five-year period) 2004–2019 (fifteen-year period)	2
<b>Share-of-growth</b>	2017–2019 (two-year period) 2009–2019 (ten-year period) 1999–2019 (twenty-year period)	3
<b>Shift-share</b>	2014–2019 (five-year period) 2004–2019 (fifteen-year period)	2
<b>Constant share</b>	2019 (a single year)	1

BEBR’s methodology produced eleven projections for each county for each projection year (2020, 2025, 2030, 2035, 2040 and 2045). From these, five averages were calculated: one using all eleven projections (AVE–11), one that excluded the highest and lowest projections (AVE–9), one that excluded the two highest and two lowest projections (AVE–7), one that excluded the three highest and three lowest projections (AVE–5), and one that excluded the four highest and four lowest projections (AVE–3).

BEBR selected AVE–5 for 66 counties, the average in which the three highest and three lowest projections were excluded. For Monroe County, BEBR selected an average of projections made with the exponential technique with a base period of five years and the linear technique with a base period of two years.

In addition, BEBR made manual adjustments to the projections in six counties in the Florida Panhandle to account for estimated population losses or slowdowns in growth due to the impacts of Hurricane Michael (Bay, Calhoun, Gadsden, Gulf, Jackson, and Liberty counties). Manual adjustments were also made in 31 counties to account for changes in institutional populations such as university students and prison inmates. Moreover, the sum of county projections equals the state projection for each year, which indicates additional adjustments.

Because no detailed information about the BEBR manual adjustments was available, no manual adjustments were made to the initial projections. Then the differences between initial projections and the BEBR projections were examined, which can reflect the manual adjustments made by BEBR. In general, the differences between initial and corresponding BEBR projections for a given county increase as the projection year increases and the maximum percentage differences for all counties fall in the year 2045. For counties that are in the adjustment list in BEBR report, if the maximum percentage difference is over 5%, a regression model was used to estimate manual adjustments made by BEBR (hereafter referred to as Type 1 adjustments). For instance, Bay County’s 2019 population estimate is heavily impacted by Hurricane Michael. Therefore, the initial

projection based on the 2019 population estimate is much lower than BEBR's projection with a maximum percentage difference of 20%. Type 1 adjustments were made for 18 counties.

**Table 2** presents population projections with Type 1 adjustments for 2020-2045. **Table 3** shows the percent differences between BEBR's projections and the projections in **Table 2**. In most cases, the differences between the two sets are below 3.0%, which indicates that our method can replicate the original BEBR population projections reasonably well and can be extended to develop future projections from 2050 to 2070 that are consistent with the 2020-2045 projections.

**Table 2 Projections of Florida Population by County, 2020-2045**

## Step 2 – Projections of Florida 2050-2070 Population by County

### State Projections

Although the cohort-component method is a better way to make population projections at the state level, the information needed to apply the method such as birth rates, death rates, and migration rates for the distant future years from 2050 to 2070 is limited. A simplified method was used to develop state projections. Three different techniques were explored:

- **Linear** – the population will change by the same number of persons in each future year as the average annual change during the base period.
- **Exponential** – the population will change at the same percentage rate in each future year as the average annual rate during the base period.
- **Logarithmic** – the population will rapidly increase in size until it reaches a certain point, called the carrying capacity. At this point, the resources are not enough to support the population.

For all three techniques, the base periods of forty-seven years (1999-2045) were used to develop the state-level projections. The population data for 1999 – 2019 in one-year increments were obtained from the annual release of Florida Estimates of Population Report by BEBR, while the population data for 2020 – 2045 in five-year increments were obtained from the BEBR Projections of Florida Population by County published in January 2020. As mentioned earlier, the medium projections were used as recommended by BEBR.

This method produced three projections for each projection year (**Table 4**). All three projection methods produced high R-squared values. The linear technique produced the most reasonable state-level projections compared to historical trends, and, therefore, linear projection results were used as the basis for county-level population projections.

**Table 4 State Projections by Projection Technique, 2050-2070**

Projection Technique	2050	2055	2060	2065	2070	R <sup>2</sup>
Linear	29,108,600	30,397,600	31,686,600	32,975,600	34,264,600	0.99
Exponential	26,782,800	28,481,700	30,288,300	32,209,500	34,252,600	0.98
Logarithmic	29,064,500	30,333,300	31,599,000	32,861,700	34,121,300	0.99

### County Projections

The county-level population projections for 2050-2070 followed the same methodology as described in the Step 1 section. Five (5) techniques (Linear, Exponential, Share-of-growth, and Constant Share) were used to produce eleven projections. Five (5) averages (AVE-11, AVE-9, AVE-7, AVE-5, and AVE-3) were calculated and different averages were used for different counties. Type 1 adjustments were applied for the same 18 counties as shown in **Table 3**. After applying Type 1 adjustments, the difference between the sum of all county projections and the state projection for each projection year was allocated to counties that did not receive Type 1 adjustments (hereafter referred to as Type 2 adjustments). Type 2 adjustments were allocated in proportion to the difference between the county's unadjusted projection and BEBR projection for projection year 2045. Finally, minor adjustments were made to eight (8) counties (Dixie, Gadsden, Hardee, Hamilton, Holmes, Jackson, Union, and Volusia)

---

whose projections were not consistent with their historical growth patterns prior to 2019 or BEBR's projected growth trends between 2020 and 2045. Like BEBR projections, the sum of FDOT county projections for each projection year equals the corresponding state projections (except for slight differences due to rounding). The final projected population by county for 2050-2070 is presented in **Table 5** together with the BEBR projected populations for 2020-2045.

Table 5 Projections of Florida Population by County (2020–2070 with Estimates for 2019)

## 7.5 Traffic Analysis

*7.5.1 Simtraffic Arterial LOS Reports and Simulation Summary*

*7.5.2 Synchro HCM Reports*

*7.5.3 HCS Merge and Diverge Reports*

*7.5.4 FDOT Level of Traffic Stress*

---

### Summary of All Intervals

---

Start Time	4:30
End Time	5:45
Total Time (min)	75
Time Recorded (min)	60
# of Intervals	5
# of Recorded Intervals	4
Vehs Entered	2655
Vehs Exited	2643
Starting Vehs	104
Ending Vehs	116
Travel Distance (mi)	2557
Travel Time (hr)	97.6
Total Delay (hr)	10.8
Total Stops	886
Fuel Used (gal)	78.0

---

### Interval #0 Information Seeding

---

Start Time	4:30
End Time	4:45
Total Time (min)	15

Volumes adjusted by Growth Factors, Anti PHF.  
No data recorded this interval.

---

### Interval #1 Information

---

Start Time	4:45
End Time	5:00
Total Time (min)	15

Volumes adjusted by PHF, Growth Factors.

Vehs Entered	736
Vehs Exited	722
Starting Vehs	104
Ending Vehs	118
Travel Distance (mi)	701
Travel Time (hr)	26.9
Total Delay (hr)	3.1
Total Stops	229
Fuel Used (gal)	21.4

---

### Interval #2 Information

Start Time	5:00
End Time	5:15
Total Time (min)	15

Volumes adjusted by Growth Factors, Anti PHF.

Vehs Entered	621
Vehs Exited	648
Starting Vehs	118
Ending Vehs	91
Travel Distance (mi)	618
Travel Time (hr)	23.4
Total Delay (hr)	2.6
Total Stops	220
Fuel Used (gal)	18.8

---

### Interval #3 Information

Start Time	5:15
End Time	5:30
Total Time (min)	15

Volumes adjusted by Growth Factors, Anti PHF.

Vehs Entered	664
Vehs Exited	649
Starting Vehs	91
Ending Vehs	106
Travel Distance (mi)	634
Travel Time (hr)	24.3
Total Delay (hr)	2.7
Total Stops	260
Fuel Used (gal)	19.4

---

### Interval #4 Information Recording

Start Time	5:30
End Time	5:45
Total Time (min)	15

Volumes adjusted by Growth Factors, Anti PHF.

Vehs Entered	634
Vehs Exited	624
Starting Vehs	106
Ending Vehs	116
Travel Distance (mi)	604
Travel Time (hr)	23.0
Total Delay (hr)	2.3
Total Stops	177
Fuel Used (gal)	18.3

Arterial Level of Service: EB #1EB

# Pedestrian Level of Traffic Stress Flow Chart

## C2T, C3C, C3R, C4, C5, & C6

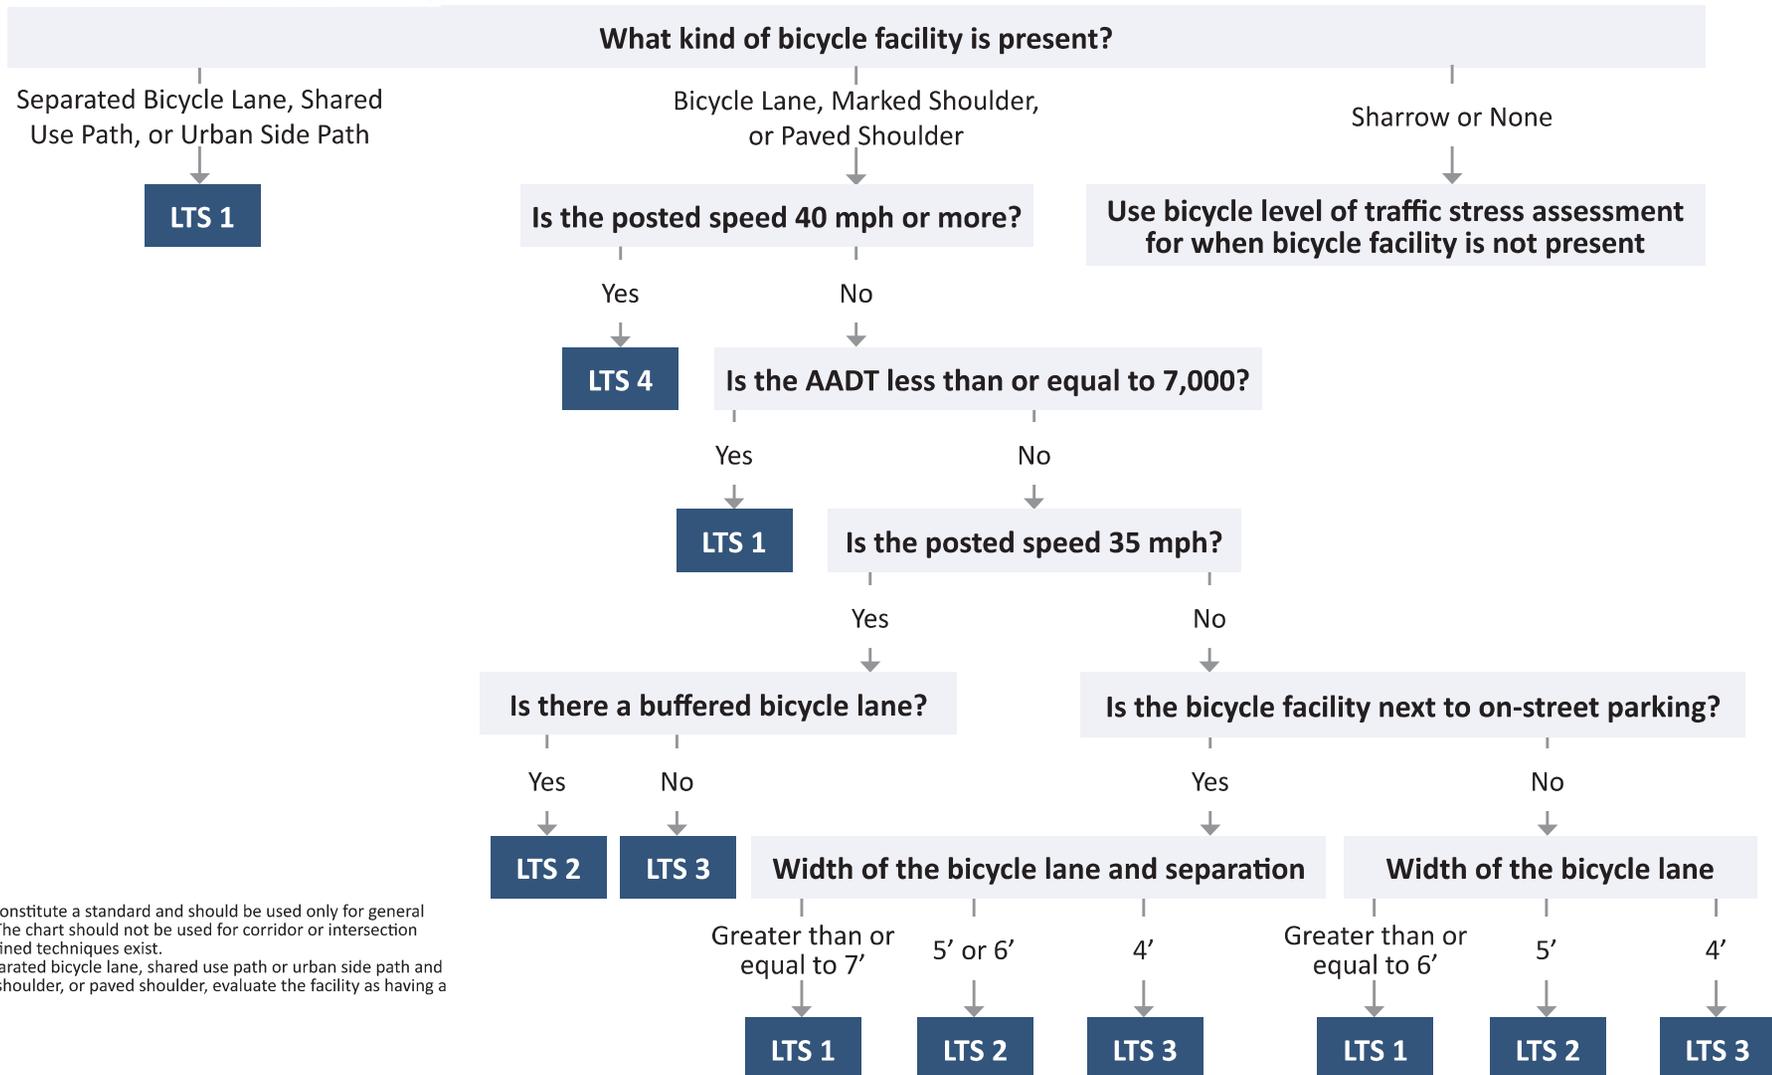

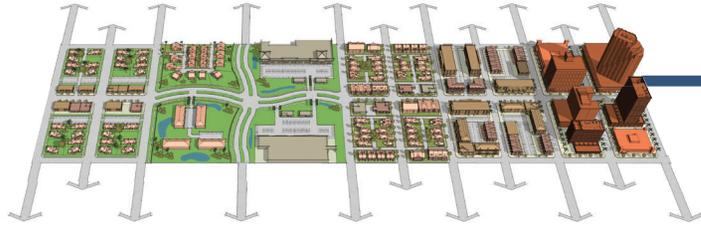

**Notes:**

- 1) This chart does not constitute a standard and should be used only for general planning applications. The chart should not be used for corridor or intersection design, where more refined techniques exist.
- 2) This analysis is conducted for each side of the road and the worst side PLTS is applied for each segment.
- 3) If the sidewalk width is less than or equal to 5 feet, the PLTS deteriorates by 1.
- 4) Separation is defined by space between the outside vehicular travel lane and sidewalk and can include bicycle lanes, unmarked shoulders, street furniture, vertical separation, landscaping, or utility strips. Vertical separation in the separation includes tubular markers, islands, on-street parking, rigid barriers, and landscaping.
- 5) Sidewalk space over 6 feet can be evaluated as part of the separation.

# Bicycle Level of Traffic Stress Flow Chart to use When Bicycle Facility is Present

C2T, C3C, C3R, C4, C5, & C6

Notes:  
 1) This chart does not constitute a standard and should be used only for general planning applications. The chart should not be used for corridor or intersection design, where more refined techniques exist.  
 2) If there is both a separated bicycle lane, shared use path or urban side path and a bicycle lane, marked shoulder, or paved shoulder, evaluate the facility as having a shared use path

Low Stress Tolerance High Stress Tolerance

**LTS 1**

**LTS 2**

**LTS 3**

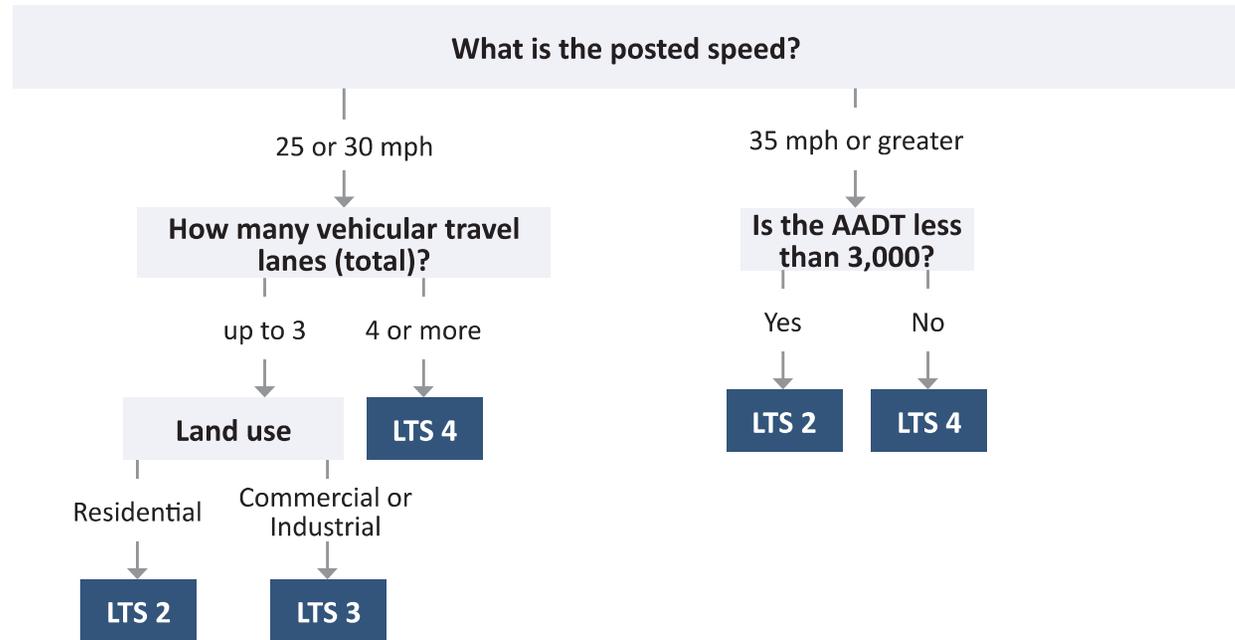

**LTS 4**

# Bicycle Level of Traffic Stress Flow Chart to use When No Bicycle Facility is Present or When There are Sharrows Present

C2T, C3C, C3R, C4, C5, & C6

Notes:  
 1) This chart does not constitute a standard and should be used only for general planning applications. The chart should not be used for corridor or intersection design, where more refined techniques exist.

## 7.6 Crash Analysis

Worksheet 1A -- General Information and Input Data for Urban and Suburban Roadway Segments

General Information		Location Information	
Analyst	C Russo	Roadway	Broad Causeway
Agency or Company	Atkins	Roadway Section	East of Gas station of eastern edge of bridge
Date Performed	10/22/23	Jurisdiction	Town of Bay Harbor Islands
		Analysis Year	2050
Input Data		Base Conditions	Site Conditions
Roadway type (2U, 3T, 4U, 4D, ST)		--	4D
Length of segment, L (mi)		--	0.35
AADT (veh/day)	AADT <sub>MAX</sub> = 66,000 (veh/day)	--	31,900
Type of on-street parking (none/parallel/angle)		None	None
Proportion of curb length with on-street parking		--	0
Median width (ft) - for divided only		15	10
Lighting (present / not present)		Not Present	Present
Auto speed enforcement (present / not present)		Not Present	Not Present
Major commercial driveways (number)		--	0
Minor commercial driveways (number)		--	0
Major industrial / institutional driveways (number)		--	0
Minor industrial / institutional driveways (number)		--	0
Major residential driveways (number)		--	0
Minor residential driveways (number)		--	0
Other driveways (number)		--	0
Speed Category		--	Posted Speed 30 mph or Lower
Roadside fixed object density (fixed objects / mi)		0	2
Offset to roadside fixed objects (ft) [If greater than 30 or Not Present, input 30]		30	8

<b>Included in HSM:</b>	No
<b>Date Added to Clearinghouse:</b>	Dec 01, 2009
<b>Comments:</b>	The number of crashes in the after period were not reported in this study, however, they have been recorded as 300 to give 10 points as a benefit of doubt for one or more of the following: (1) number of miles/sites in the reference/treatment group, (2) number of crashes in the references/treatment group, (3) reporting AADTs for the aggregate dataset but not for the disaggregate dataset used for CMF development.
